Step 3: Segmentation. We segment a log file into interesting pieces to provide basic units for pattern matching. The literature suggests several alternatives, such as session (for multi-session log files) or chunks of time (perhaps standardized, as in [Chen et al. 95]).

Based on student interviews, we determined that the sequence of actions involved in answering an inquiry question was key to understanding how these students use STC in their chemistry course. As a result, we segmented the log files by question. For each log file, we first combine all actions that occur between initialization and the first visit to any question; then we create segments corresponding to the sequence of actions for a given question. A new segment is created when the student goes to a new question.

The first five Acids & Bases segments for a sample student are shown in [Tab. 2]. The first two lines reveal that this student visits a large portion of the module before visiting the first question ("overview" refers to a "table of contents" list for the questions).

ID	Module	Question	Sequence
5852	4	none	mcccmcv
5852	4	overview	qccmccffmccvccmcvccmcacacmccvcvcmcvcccmcccmcmcvcvmcmccccffq
5852	4	1	qCqrCCqrr
5852	4	2	qmq
5852	4	3	qrr

Table 2: Sample Segmented Sequences

Our segmentation process reduces the 121,390 abstract events to about 18,500 segments, ranging in length from 1 to 150 with an average length of 7 events. The complete transformation process (for 200 student log files) takes 10 to 15 minutes.

3.2 General Pattern Search using MacSQEAL

To initiate a pattern search, MacSQEAL allows the researcher to specify:

- match criteria (e.g. match("^qr+$") and (module=4) and (question=4))
- items to be displayed for each match (e.g. "Line" or "count(C)")
- criteria for computing a frequency count for the matches (e.g. "count(C)")

The researcher specifies the match criteria using extended regular expressions – a general pattern matching a set of sequences. Perl regular expressions contain special characters that identify when elements or sequences can be selected from a set of choices (appear within [ ]), appear at the beginning (^) or end($) of a sequence, occur zero or once (?), zero or more times (*), one or more times (+), or a range of times ({3:6}). For example, the pattern `^qC+[qm]?r$` matches all sequences that begin (^) with q, are followed by 1 or more Cs, an optional q or m, and finally end ($) with an r.

Using regular expressions has several advantages: they permit the researcher to selectively ignore events without recoding. For example, the pattern `qm?cr` matches both `qmcr` and `qcr`, permitting the researcher to establish the `m` as not essential to the pattern. They also allow the researcher to specify a family of equivalent patterns. For example, the pattern `qC+r` matches all sequences with only one or more `C`s between `q` and `r` (`qCr, qCCr, qCCCr`, etc.). The pattern can determine which sequences are a match, but it can also be used to extract portions of the sequence to be tested or counted. For example, `^q([cCmaevq]*)r` matches everything from the initial `q` up to the first `r`. The portion of the expression in parentheses is saved in a special variable which can be referenced for displays or counts by the keyword `paren`. For example, when used in conjunction with `^q([cCmaevq]*)r`, the quantity `length(paren)` can be displayed in a histogram to show the lengths of investigation which precedes the initial attempt at answering a question. For a more comprehensive discussion of the extended regular expression capability of Perl, see [Schwartz 93].

A MacSQEAL query generates two kinds of output: a list of the items specified to display for matching lines, and the frequency count data. Both are in a tab-delimited format, which can be easily imported into graphing or statistics programs.

3.3 Examples

We have used MacSQEAL to extract two kinds of information: aggregate data (e.g. counts for a given pattern) and more complex queries. We will show one example of each.

Aggregate Data

One of the innovations of MacSQEAL is that aggregates can be explicitly tied to sequences. From the interviews, we know that some students are "question-driven": they read the question, and then use key words to pick content cards to visit, before they attempt to answer the question. We investigated this phenomenon for Question 4 in Acids & Bases [Fig. 1]. [Fig. 1a] shows the number of relevant content cards visited between reading the question and initial revision. However, a count of cards does not reveal how successful students are at identifying "relevant" cards. [Fig. 1b] displays the same query, with a different frequency count; this time showing the percentage of relevant cards in relation to total cards visited before initial response.

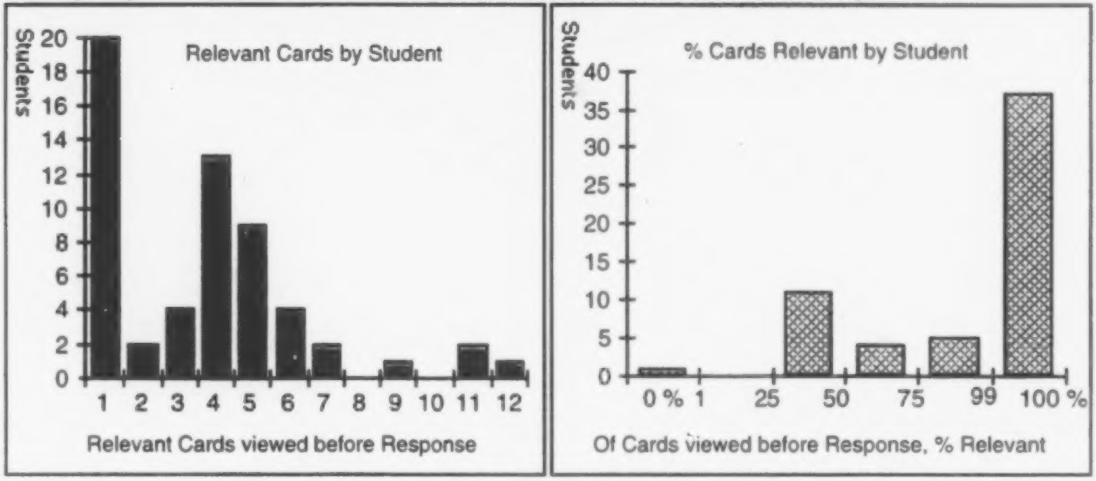

Figure 1: Question-Driven Students in the Acids & Bases module, Question 4

The query reveals 58 students with this "question-driven" pattern. The MacSQEAL query is as follows:

select: ^q([cCmaevq]+)r and (module=4) and (question=4)
frequency count: [Fig. 1a] countin(C, paren)
or [Fig. 1b] countin(C, paren) / (countin(C, paren)+countin(c, paren))

Complex Queries

In examining the responses for the Acids & Bases module, we were surprised by the number of students who revise (more than 40% on each question; ranging from 40% to almost 90%). We also identified a question (4) with an exceptionally high error rate, along with another question (6) with the second highest number of

BEST COPY AVAILABLE

incorrect choices and revisions. We decided to examine patterns of use on these two questions in comparison to one another and to the other questions, to see how they might differ.

We use the following query:

select: r([mqaev]*[cC]+[mqaev]*)+r and (module=4) and ((question=4) or (question =6))
frequency count: module:question

The pattern "r([mqaev]*[cC]+[mqaev]*)+r" corresponds to "students who visit one or more content cards between revisions" – [mqaev]* means there is an optional (zero or more) visits to the question, the map, or other media. This query returns 75 students; 47 of these have the pattern only for question 4, 14 show the pattern only for question 6, and 14 show it for both questions. An interesting follow-up question is whether the 14 who exhibit the pattern for both questions differ on some important metric (such as previous experience in chemistry, or enrollment in the lab class) from those who use it for only one question, or not at all.

4 Discussion

4.1 Contributions

MacSQEAL facilitates sequence exploration by supporting fast ad-hoc queries over large data sets. By leveraging extended regular expression technology, the tool is able to match families of patterns as specified by the researcher. We integrate MacSQEAL and accompanying data transformation tools into a novel method for initial log file investigation.

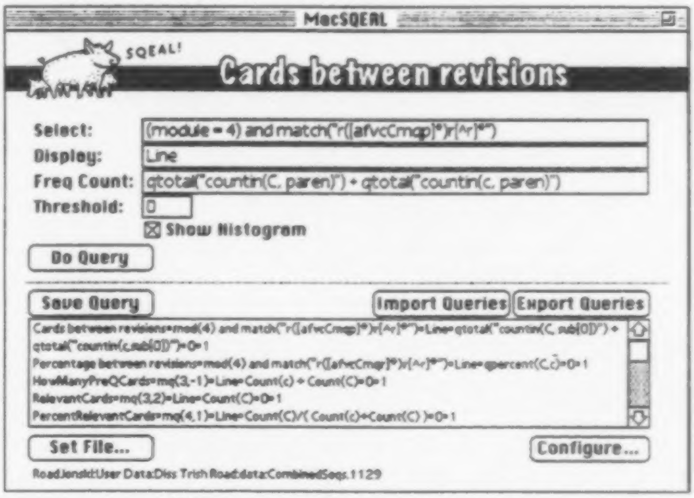
We believe that our method complements other approaches to log file analysis. Because of the speed of execution, it is possible to identify trends in the data, focus efforts on promising groups, and then apply other more formal, rigorous statistical techniques. The greatest value comes from a grounding in actual observations of, or interviews with students situated in their usage. This allows the researcher to understand some of the meaning behind events, and determine what may be important to investigate more fully.

4.2 Limitations

MacSQEAL is an exploration tool, not a discovery tool. Without hypotheses grounded in other analyses or data sources, MacSQEAL should not be relied upon for discovery. But for exploration – in our experience – it excels.

Because this work is both preliminary and exploratory, we do not know if regular expressions identify the most important natural groups. Maybe it is not as important that students match in their patterns of use as that they spend the same amount of relative time on one component, or that they exhibit similar misconceptions in their answers.

The process we describe is general, but — at least currently — the transformation tools are specific to our log files, and the format of the MacSQEAL input file is only informed by our data (we may need to add additional columns or features to handle data from other research groups).



Select: (module = 4) and match("r([afvcCmqp]*)r[^r]*")

4.3 Future Work

MacSQEAL has a HyperCard front-end consisting of a fill-in form that is used to specify queries [Fig. 2]. In the future, we hope to add a more graphical interface, and to integrate the query mechanism more closely to graphing software (e.g. automatically generate the appropriate bar charts from frequency counts).

As part of the larger study examining student use of *Seeing Through Chemistry*, we are using MacSQEAL to extract overall patterns of use for each question for each student – these will then be part of a vector characterizing the student that will be used in a cluster analysis. More specifically, we will examine the relationship between prior chemistry knowledge, patterns of use in STC, and quality of inquiry question explanations.

Abstract: The growing Internet accessibility for educational purposes has raised a range of issues that concern not only children's emotional safety and the beneficial use of limited resources but also their development of critical skills in searching, retrieving, and using information media. As interactive electronic media become more pervasive in children's school and home lives, it is especially important that even young children are developing these skills so that they can build a solid foundation for their later learning. As a case in point, this paper describes and discusses an educational intervention with over 200 elementary school children ranging from ages 6 to 13. During a five week period, students from six separate classrooms in the Los Angeles area built a collaborative World Wide Web directory. The resulting "SnapDragon" Web site is an annotated index by children for children . One goal of this intervention was to help children develop criteria of "information relevancy" as they were reviewing sites and writing their evaluations. A preliminary analysis of the evaluations indicates that many children placed a primacy on "visual relevancy" in contrast to "text relevancy" -- a result which reflects the issue that many web sites are not written in child-adequate language thus making it difficult especially for young children to gather pertinent collecting information about their world and culture. We furthermore discuss issues regarding children's information searching skills and collaborative models in classrooms with limited Internet access.

Introduction

The rush to connect schools to the Internet is in full swing. In the report "America's Children & The Information SuperHighway" Lazarus & Lipper (1994) concluded that it is critical that all children have access to the Internet and furthermore that children's needs be given a high priority as technology strategies are developed and implemented. Netday'96, a non-profit initiative, aimed to connect twelve thousand California schools to the Internet in March 1996. While many schools have begun to give students Internet access, allow them to browse and search information, and to build their Web pages, it is still an open question in which ways Internet activities can effectively be used and integrated with other classroom learning.

The "SNAPdragon" project was created to investigate how children can interface with the Internet by asking them to build an annotated directory of Web sites for other children. The project's general goal was to build children's information literacy skills and to develop children's understanding of the value and relevancy of the information they gathered from various sites. For that purpose we asked them to write annotations to the sites they had visited.

Furthermore, we wanted to provide children with a context in which the search and retrieval of information would no longer be an isolated experience but connected to their classroom learning and to a larger social goal -- to share their insights with other children. Instead of keeping the annotated search results confined to individual classrooms, we implemented a collaborative index that could be accessed by other children through the World Wide Web. We also saw the construction of an information structure such as an index as another powerful way for children to gain better understanding of existing Web directories such as Yahoo, etc.

By observing students' efforts we could start to answer questions such as: Can children effectively use the search engines currently available? Can they find appropriate resources in a directed search? Can they evaluate and use the selected resources? The SNAPdragon project was a first step and only a few classrooms were involved in the preliminary research. We hope that the insights gained in this study will help teachers and researchers to design better learning environments in regard to classroom management, children's information search and evaluations, and students' motivation and interest.

Project Overview

For the implementation of the SNAPdragon project, we took advantage of an existing consortium of Los Angeles schools called The School Networking Action Project (SNAP). SNAP was started by the schools and Apple Computer's Learning Concepts Group. It was funded largely by Pacific Bell's CalREN (California Research and Education Network) initiative to afford California schools high speed networking capabilities. Pacific Bell and a series of other business and industry partners provided the participating schools with high speed phone lines, servers and Internet access. At the beginning of this project (January 1996) most of the schools (but not all their classrooms) had been connected to the Internet. But there had not been extensive use of this connectivity due to a series of technical obstacles.

To begin the Web project collaboration, a call went out to all the SNAP schools in November 1995, asking teachers and technology coordinators to send in applications indicating their interest. Schools were informed that the SNAPdragon project would run concurrently with an UCLA graduate seminar in which students would not only examine and discuss the educational benefits of telecommunication activities but would also be required to hold an internship in a local school. By January we had received over 20 applications. Teachers, UCLA graduate students and the seminar instructors met once in January to get to know each other and to select the sites. For this project, only six classrooms participated because we wanted to match each classroom with one UCLA graduate student or researcher. The classrooms were selected in such a fashion that at least one classroom from each SNAP school was represented. The following table provides an overview of the grade levels, number of students, number of computers with Internet access in each classroom (see Table 1).

TABLE 1: Overview of Participating SNAP Classrooms

School Name	Grade	Students	Internet-Enabled Classroom Computers	Search Topic	Curriculum Integration
Open Charter	3/4	64	1	City Building	yes
Westwood Charter	5	9	1	National Parks	no
Seeds UES	1/2	33	4	Airports/Iditarod	yes
Seeds UES	1/2	31	6	Ocean Animals	yes
Seeds UES	3/4	30	15	Black History/ Poetry	yes
Hawthorne School	6	29	1	Ancient Egypt	yes

Each classroom had a different physical setup, a different number of students, and a different search topic. In spite of all these differences, we hoped that the collaborative activity would provide enough "glue" to bring all the students and their teachers together. The following summaries provide an overview of how the SNAPdragon project was implemented at three of the sites. A complete reporting for each site can be found on the Web at http://www.gseis.ucla.edu/SNAP/report.html.

The Open Charter School is located in an ethnically and socioeconomically diverse section of the city of Los Angeles. The school has enjoyed a high degree of academic autonomy over the years because in the 1980s it received support from Apple Computer to install computers in every classroom. The SNAP classroom, a combined third and fourth grade class involved in this project, had two teachers, 64 children, and one Power Mac 6100 linked to the Internet via a 14.4 baud modem. We dialed into a server at UCLA for access.

The class was involved in a yearlong project of building a city of the future, called City Building Education(tm) (Nelson, 1984). Since the children were already organized into various commissions for building the city, we structured the Internet search sessions around the already formulated commission schedules and themes.

On most Mondays and Fridays in February 1996, two hours of the school day were set aside for Internet time. We managed the Internet searches by having four of the commissions take half-hour turns sitting in a circle of chairs around the computer. The search session was structured by the researcher, who came to class equipped with URL address lists and then looked up the Web sites as the children observed. This strategy was adopted because it seemed the most efficient way to describe how the Web worked to large groups of children. As the sessions evolved, the students took turns working different "jobs" related to the search. There was a "mouse master," a "reader," and a "scribe" to record each commission's annotations. These jobs were rotated for each Web page search.

Internet search sessions were focused on critiquing the Web pages. These sessions challenged students to move beyond simple "I like it" and "I don't like it" answers and toward offering evidence for their opinions.

The sessions also gave students a chance to practice reading and writing. Issues of vocabulary came up repeatedly because many Web sites included difficult words.

The Web searching process revealed a dearth of "child-friendly" sites, particularly concerning subjects considered too technical for kids, like new transportation technology. We found that including the word "kids" in searches usually turned up more colorful, interactive sites in plain English. By far, these were the children's favorites. In total, the children received 9.5 hours of Internet time. The preparation time outside of the lesson was about equal to in-class time, divided equally between searching for good sites and troubleshooting technical problems.

The highlights of our findings were that: 1. children prefer Web sites with high visual content and short, simple textual content; 2. children are eager to create their own work and put it on the Internet; 3. children want to use the Internet for recreation, long-distance communication and class project research; 4. children are inspired to talk about their social views and surroundings when they view Internet sites featuring children's artwork and photographs from other places; 5. children would like to see more animation and interactivity on the Internet; 6. children have a low tolerance for long download times; and 7. children require support in their search process, particularly with scanning text and using hypertext links.

The Westwood Charter School is a public Los Angeles City School located in a middle class, mainly single family dwelling neighborhood. Nine students from a fifth grade classroom participated. The ethnically diverse group consisted of 3 girls and 6 boys all of whom were ten or eleven years old. The children were comfortable using computers and had adequate typing and spelling skills. Many of them had access to computers at home. The children's teacher encouraged the use of technology in the classroom and was herself quite knowledgeable. The school was fortunate to also have a very knowledgeable and enthusiastic technology coordinator who had previously worked in the software industry.

The children met for two hours once a week for six weeks. Generally the first part of each session was used for discussion, mini-lessons and problem solving. Since there was only one computer available, the children were divided into self selected collaborative groups of three. The children selected the topic "National Parks" and the three groups took turns searching the net for sites containing information about National Parks.

In the first two sessions the children explored the net. They learned how to navigate, perform searches, use bookmarks, visit sites and use hot buttons. As the children became more skilled, they were exposed to additional search techniques and helped to perform more directed searching.

The children preferred sites with pictures and colorful graphics. Sites composed of only text or with more than 1 or 2 pages were left unexplored and in general children rarely spent more than a few minutes at any one site. The most popular site was the Hawaii Volcanoes National Park site. It contained a map of the caldera superimposed over a photographic image of the area. The colors were vivid and most of the names and locations on the map were hot buttons that linked the visitor to a brief description of the selected feature or area. These hot button encouraged the children to explore at a greater depth than if the information had been contained in a single site. While the children were enthusiastic about visiting Internet sites, they resisted writing annotations for the directory. Only after they saw other children's contributions were they willing to put effort into constructing the annotations.

Limited observation of these fifth graders suggests that children, age 10 and above, are capable of finding resources on the net. Their typing, spelling, vocabulary, and Boolean logic skills do come into play and can limit their ability to find appropriate resources. However, with direction, they are able to formulate search arguments, narrow or broaden a search depending on the previous search results; and they are capable of comprehending hierarchies when they have adequate base knowledge. Just as in the library, where the children often need the assistance of a librarian to find the materials they need (and so do most adults), children searching the net will also need an intermediary to help them track down appropriate sites. The level of comprehension and interest would suggest that the Internet may be a valuable resource for children.

The primary classroom of Mr. Raul Alarcon at Corinne Seeds University Elementary School has 31 bilingual (English/Spanish) children age six to eight. This classroom contains six networked Macintosh LCIIs which have direct Internet access from UCLA. Netscape's Navigator (version 1.1) Web browser is installed on each computer. The children spent a total of 10 sessions using the World Wide Web. In addition to the researcher and the classroom teacher, a school librarian was also present and available for help at each session. Each of the sessions was approximately 30 minutes long. Some children casually used the computers in the morning before school started or at other free times throughout the week. A few children also had computers available to them at home.

The children were studying "ocean life" over the course of the semester. Prior to the introduction and use of the Internet, the class discussed sea life, read about fish and ocean mammals, did some library research, and collected appropriate books to have available in the classroom throughout the duration of the project. Each student selected one ocean fish or mammal to learn more about. The children planned to use the World Wide Web to find more information for their sea animal research reports.

The children spent several sessions exploring a list of Web sites the adults had found in advance to determine each site's relevance to their particular ocean animal. The children were very eager to share their findings with one another. If one child found an interesting site which did not contain information on the animal they were researching, but thought the material would be of interest to a friend, they would tell the other child. They also printed and exchanged relevant pages with one another. Some children had more success than others in finding information depending on what fish or mammal they picked. There was far more age appropriate information on dolphins, sharks and whales than for seahorses, star fish or eels for example.

The children learned that the information they found on the Web could be submitted by other adults or by children and that the information came from all around the world. As Mya (age 7) and I waited for one Web page to download I asked her what she thought about waiting. She said, "Well, since there's just one world -- its gotta be coming from somewhere in this world, but it could be coming from another city or country."

We wanted to get the children to think critically about the information or perhaps the misinformation they might be receiving. As with books and other "authoritative" media, the children were quick to assume everything they found about their sea animal on the Internet was correct, just because it was there. Many of the information providers may not have accurate information or the ability to communicate it effectively to children, however.

The children's annotations of the Web sites played a secondary role in this classroom project. The children did not begin to evaluate the sites until the third week into the study. Because of the children's young age we could not ask them to write up annotations on their own. I sat with the children one at a time to get their selections for the "best site" relevant to their sea animal. In general, the children had difficulty articulating why they picked one site above the others. The resounding reason was that "it had lots of information", or "it had good information".

The children were generally highly accepting of all of the Web sites and believed they were all helpful and interesting. Their favorite selections were generally Web pages created by other children.

When the SNAPdragon site became "live" the children were delighted to see their own comments posted on the Web. It gave them a great sense of pride to know that children and adults from around the world could read their comments and also benefit the information provided in their "favorite" sites.

Summary

In March 1996, the SNAPdragon project was brought to a temporary completion. We concluded our intervention with another meeting in March to which all the participating teachers, even some students and other interested researchers and visitors came to share their experiences. While the SNAPdragon project was not a systematic study of different classroom settings and students' information literacy skills, we nevertheless gathered some valuable insights for future Internet activities.

Internet Access. As noted in many policy reports and discussions, access to the Internet is an important issue, if only for the limited resources of computers, phone lines and wiring. While providing all students with computers might not be possible, we found that working with even one Internet-accessible computer turned out to be feasible given certain classroom arrangements. In one case (Open School) we took advantage of existing team structures, i.e., the different city building commissions, and used the commissions and their topical interests to direct the Internet searches. In another case (Hawthorne School), we adopted a "tutoring" model in which the most Internet-experienced students became the tutors to teams of their classmates guiding them along their searches. In other classrooms, we built teams of students that searched together. In our effort to integrate the SNAPdragon activity with existing classroom activities, we found that (with some exceptions) these collaborative arrangements worked well and amplified students' learning of how to work together.

In our classroom observations we found considerable differences between those students who had opportunities at home or other places to familiarize themselves with computers and different tools and those for who it was a first experience. These differences appeared as early as in the primary elementary grades with students of ages 6 and 7. Expertise in manipulating the mouse, identifying interface elements such as buttons and menus, and finding keys on the keyboard varied among students.

We also were hesitant at first about the inclusion of primary elementary school students in the SNAPdragon activity. It was unclear how these young students would be able to use the Web for their learning purposes because of their beginning writing and reading experience. One situation concerned the typing of the long string of HTML addresses. The children often typed the URLs incorrectly and were prevented from connecting to their desired Web site. The typing activity also took valuable time, leaving less time for the children to spend with the content material they required for their reports. Some of us felt it was a waste of time for the children to labor over the cumbersome, meaningless strings of letters and symbols. Our recommendation is to have children use bookmarks for either directing their searches or for marking "valuable" sites.

Information Searching. One of the main goals of the SNAPdragon project was to provide a context for children to exercise their information searching activities for a larger social goal-to build a collaborative annotated Web directory for other children. While the younger students were not engaged directly in searching sites on the Web, the older elementary school students conducted some searches and used different available Internet search engines. In initial efforts, students simply put in terms such as "National Parks" and expected the results to be their end of their searches. We found that asking students to pick different search engines, to input the same terms, and to compare and to discuss the different search findings resulted in a better understanding of search functionality. These sessions seemed to help best when introduced after students had experienced some frustrating search results. As some previous research on students' information search abilities has found, students have difficulty developing extended search strategies as well as developing criteria for satisfactory end results.

Information Selection. Selecting good sites was also difficult for students. Titles and descriptions returned by search engines were sometimes misleading and difficult for the children to evaluate. After some discussion, students improved their ability to identify sales and marketing sites versus informational sites. This problem was also compounded by their reluctance to read or scan the list of results. It appeared that only titles were used to decide which site to visit. Since the system was often slow, picking the wrong site precluded visiting additional sites.

The Web searching process revealed a dearth of "child-friendly" sites. By far these were the students' favorites, but even they didn't really measure up to students' high standards. The students demanded higher production values: quality audio, video and heightened interactivity. The attractiveness for the later aspect showed itself in a site which students found in their searches about "ancient Egypt": they could submit their name to the site and have it returned in hieroglyphs. This was by far one of the most popular sites. Sites without graphics or pictures were almost always deemed boring and uninteresting and text-only sites were not explored. It was from reading the evaluations written by the students that it became evident that students placed a primacy on visual information on the Web sites and had more difficulties in evaluating the text-based content.

Information Evaluation. Creating annotations for this index, dubbed the SNAPdragon page, introduced students to the practice of critiquing other people's work. In critique sessions, students were challenged to move beyond the simple "I like it" or "I don't like it" statements and offering evidence of their opinions. Their initial annotations were for the most part poor and it required a significant effort to persuade them to actually evaluate the site. They did not see the point or value of writing annotations. Two factors changed this. Often the researcher or teacher reminded students that their efforts would be seen on the Web and that they were representing their school. The second factor had a greater effect. When the students were actually able to visit the SNAPdragon site and read other children's write ups the task became important. In one case, a student wanted to write, "this site sucks"; only after he became aware that other students from all over the world would be able to read this annotation, he decided to expand his commentary. These sessions also gave students a chance to practice reading and writing. Issues of vocabulary came up repeatedly because many Web sites included difficult words.

Conclusions

In general, students' interest in Internet activities was high. The students, of course, were enthusiastic since "surfing the net" is the cool thing to do. They all expected that they would use the Internet in the future probably from home and several students talked about their parents giving them access to the Internet. For future activities, we recommend to build on children's interest in the Internet by providing them with opportunities to represent themselves to this community. SNAPdragon became one way to do so. We would probably start out by asking children to write something about themselves, their class or school and use it as a first submission to a site. Having an "Internet" identity seems to be of great value to students.

While the project in its first installment was initiated and organized by adults, we think that having the students handle all aspects, from creating the site and collecting annotations to indexing the entries will prove to be the best learning experience. In fact, one of the most valuable learning experiences for the members of the university course appeared when we were confronted with the task of categorizing the first SNAPdragon submissions. Due to the different search areas, content ranged from national parks to transportation and poetry. We had extensive debates which category names to choose and how to index entries-tasks faced by any professional information specialist. By default of any better solution, we adopted the Dewey classification system. While the categorization of musical instruments, animals and plants is a common activity in elementary classrooms, students usually do not deal with the wide range of issues that appeared in SNAPdragon indexing, or for that matter with any directory. In retrospect we wished that the students had had this opportunity. Becoming information literate, or better, fluent, means more than knowing how to search for the right information. It means understanding all of the issues ranging from the making, to finding and using of information.

The Nature of Conceptual Change in Astronomical Phenomena in the PICCO Environment

MARJATTA KANGASSALO
University of Tampere, Department of Teacher Education
P.O. Box 607, FIN-33101 Tampere, Finland
Email: kamaka@uta.fi

Abstract: This article will describe conceptual change in children's conceptual models of astronomical phenomena when children explored the phenomenon using a pictorial computer-based simulation, PICCO. The exploration of the phenomenon by children was based on children's own interest, and occurred spontaneously and independently without any adult involvement. The selected phenomenon for PICCO was the variations of sunlight and heat of the sun as experienced on Earth related to the positions of the Earth and sun in space. The children had no formal instruction before or during their exploration process. The children taking part were Finnish first-graders who were about seven years old. Conceptual change in the children's conceptual models seemed to occur in the direction of the currently accepted scientific knowledge. Conceptual change has been compared with Thagard's taxonomy of kinds of epistemic change and Vosniadou's research results of conceptual development in astronomy.

Introduction

In this article, conceptual change in astronomical phenomena will be examined in the PICCO environment. PICCO is a pictorial computer-based simulation which has been designed and constructed for the author's investigation. Conceptual change has been studied in a child's conceptual model, concerning a selected natural phenomenon, when a child is exploring the natural phenomenon by using PICCO. In this investigation a conceptual model is seen as a mental construct, which is developing during a child's cognitive action. A child's cognitive action like perception, remembering and thinking processes, as well as activities connected with them, are primary processes in the developing of a child's conceptual model concerning a given natural phenomenon. Correspondingly, the conceptual model of a given natural phenomenon forms a basis for a child's cognitive activities concerning the phenomenon in question. By means of a conceptual model through visual images it is possible, for example, to examine a phenomenon, its objects and their qualities and spatial and temporal relations, both events taking place within the phenomenon, and also to follow the sequences of the events. In addition, a conceptual model makes it possible to explain and predict a phenomenon. [Compare Nickerson, Perkins, Smith 1985.] The more developed and integrated the conceptual model of a phenomenon, the better basis it gives to cognitive activities concerning the phenomenon in question.

This paper concentrates on the nature of conceptual change in the children's conceptual models, which occurred when the children were exploring the phenomenon by using PICCO. In the examination, the subject of the interest has especially concerned the following questions: How a child's conceptual model concerning the selected phenomenon constructs, when a child can spontaneously and independently, from the basis of his or her own interest, explore the phenomenon using the PICCO program. Further, how and in which direction conceptual change occurs in the multimedia environment and in this case, especially in the PICCO environment. These afore-mentioned questions are important and of significant interest. This is because previous research concerning the conceptual development in astronomy has suggested that children proceed during their knowledge acquisition towards the scientific knowledge through many kinds of misconceptions. In addition, the abandonment of the misconceptions has proved to be very difficult.

The children taking part in the present research were Finnish first-graders who were about seven years old. They had no formal instruction before or during their exploration process of this natural phenomenon at school. Immediately after the research period, during the school term this topic was also dealt with. During the research period, the children had the possibility of exploring the phenomenon by using the pictorial computer-based simulation over four week period in a day care centre after school. In the research group there were eleven children.

The following chapter will briefly describe the pictorial computer-based simulation, PICCO. Afterwards the nature of conceptual change in the children's conceptual models will be examined. After this, conceptual change in the children's conceptual models in relation to conceptual development in astronomy will be compared.

Description of the Pictorial Computer-Based Simulation - PICCO

This chapter briefly describes the pictorial computer-based simulation, PICCO. The selected natural phenomenon for the pictorial computer simulation was the variations of sunlight and heat of the sun as experienced on Earth related to the positions of the Earth and sun in space. In the simulation, it is possible to explore the variations of sunlight and heat of the sun and their effects on the Earth in a natural environment and the origin of these phenomena from the basis of the interconnections and positions of the Earth and sun in space. The simulation concentrates on phenomena which are close to everyday experiences of children, such as day and night, seasons, changes in the life of plants and birds etc. The simulation program has been implemented in such a way that the knowledge structure and theory of the phenomenon are based on events appearing together with the phenomenon in question, and these events are illustrated. In the simulation, all events and necessary elements are represented as pictures and familiar symbols. On the Earth level, the pictorial simulation represents the surrounding world, its phenomena and objects in a very natural and realistic way. In exploring the phenomenon on the space level, the interrelations of the Earth and sun are represented with the help of an analogous model. The selected place on Earth from where the phenomenon has been modelled and simulated for a computer is the suburb of Lentävänniemi in Tampere, in Finland.

The exploration of the phenomenon starts in Lentävänniemi on 1st January at midnight. On a big screen a dark, snowy, winter landscape in a southerly direction is seen at that moment. The exploration of the phenomenon can be continued by using icon pictures under the picture of the landscape, for example, a clock, a pictorial calendar, a picture with different points of the compass and a space shuttle. The exploration of the phenomenon can be continued in many ways; hour by hour, day by day, month by month, at different points of the compass and so on. At any moment it is possible to take a space shuttle and to look at the interrelations and positions of the Earth and sun on the space level. On the space level it is also possible to explore the interrelations and positions of the Earth and sun by using icon pictures which show the time in the same way as on the Earth level. At any moment, it is possible to choose how to continue exploring. Exploring can proceed at any moment using the existing alternatives. Two displays of the screen can be seen as examples in Figures 1 and 2. The pictures were drawn by Aila Penttiä.

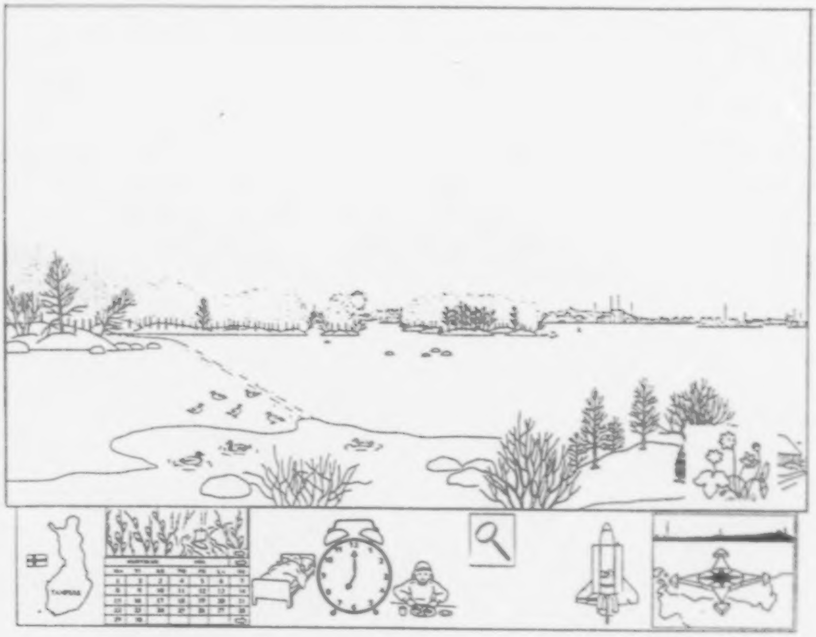

Figure 1. 1 April at 7 o'clock in the morning toward the east a hepatica being enlarged

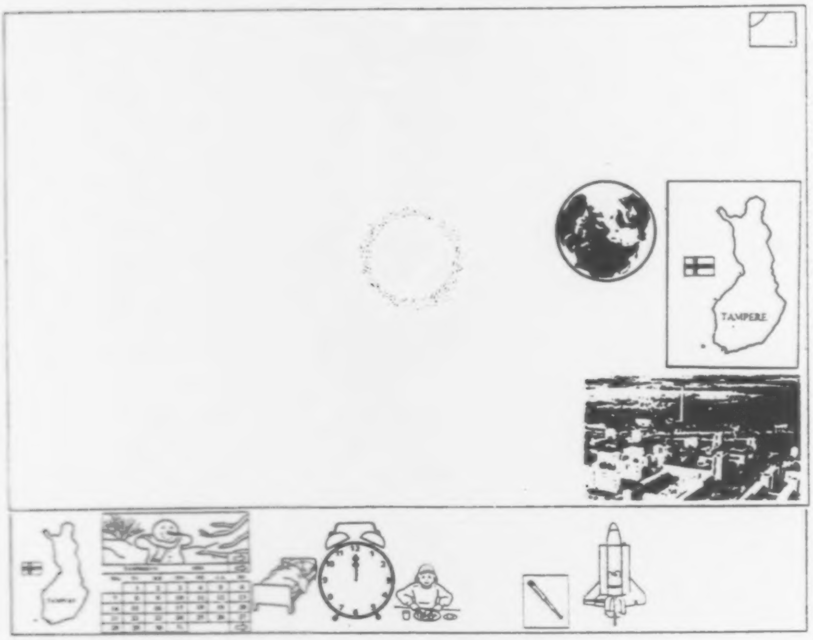

Figure 2. 1 January at 12 o'clock, at the space level with a bigger earth, the map of Finland and the aerial photo of Tampere

When exploring on the space level, the Earth, rotating around its axis and revolving around the sun on its elliptic orbit, appears on the screen. When exploring the phenomenon on the Earth level, the following may appear on the screen: the changes in dark and light during the day with an accuracy of one hour, the sun's positions in the sky every hour, the place and time of the sunrise and the sunset every day all year round, typical plants, birds and animals according to seasons and so on. With the help of the icon pictures, binoculars, a magnifying glass and microscope, it is possible to explore flowers, trees, leaves, insects, birds, spores, animals and so on in more detail. On the screen, a selected object is enlarged. On the space level, with the help of a telescope, it is possible to enlarge the earth so that, for example, Finland is seen more clearly. From this picture of the Earth, it is possible to continue further and to see the map of Finland, and finally an aerial view of Tampere. In the simulation, it is also possible to explore the relative size of the Earth and sun and to get an idea of the distance between them. The position of the Earth in the whole solar system can also be seen on the screen. The pictorial computer simulation is constructed so that it is very easy to use and it does not presuppose an ability to read or write. A pictorial computer simulation [Kangassalo 1991] is described in detail in the articles by Kangassalo [Kangassalo 1992, 1994, 1996].

The Nature of Conceptual Change

Before and after the exploration of the natural phenomenon using PICCO, the children's conceptual models were elicited by using specifically designed procedures for this investigation. The eliciting of a conceptual model was achieved using procedures aimed at stimulating a recollection of the natural phenomenon in question. A child modelled the natural phenomenon from the basis of recollections and images through action, pictorially and verbally using different tasks. The modelling took place by showing, drawing, modelling and explaining. The phenomenon forms the wholeness which contains many, integrated phenomena and their interconnections. The

BEST COPY AVAILABLE

main interest in this research was to study a child's conceptual model of the selected phenomenon, emphasizing relations and their changes in a child's conceptual models concerning the phenomenon in question. Regarding the natural phenomenon in question, attention was paid to the variations of sunlight and heat of the sun on the Earth, the interconnections of the Earth and sun in space, and interrelations of phenomena on the Earth and in space. In addition, attention was paid to the size, form and distance between the Earth and sun.

Before the use of the simulation the children's conceptual models were at very different levels. Some children's conceptual models of the phenomenon were quite undeveloped, and some others' were well developed. Only some children's conceptual models contained a clear misconception. During the use of the simulation in the children's conceptual models some changes occurred. The most significant change was that the interconnections of different phenomena and entities began to be constructed and the construction seemed to follow the currently accepted scientific knowledge. Concerning the natural phenomenon in question the main direction of construction by children tends to be as follows:

1. The Earth begins to revolve around the sun.
2. Seasons are organized in the everyday world and are connected to the positions of the Earth and sun in space.
3. The alternation of darkness and lightness on Earth is seen to have resulted from the turning or revolving of the Earth in it's orbit.
4. The alternation of darkness and lightness and the succession of seasons, has been seen to have resulted from the rotation of the Earth around its axis once every 24 hours while the Earth is revolving around the sun, a circuit around the sun taking place once a year.
5. Before the use of the simulation, the sun was revolving around the Earth in three children's conceptual models but, however, after using the simulation, in two out of the three conceptual models the sun no longer revolved around the Earth.

Next, the nature of conceptual change will be examined according to the afore-mentioned direction of construction in children's conceptual models, concerning the phenomenon in question. In examining changes in children's conceptual models, the most significant change concerned the interconnections of the Earth and sun. The Earth began to revolve around the sun in those children's (6/11) conceptual models where, before the use of PICCO, the spherical Earth was either motionless or it turned, spinned or swayed in one place in relation to the spherical sun or where the examination of the phenomenon occurred only on the Earth level. The revolving of the Earth around the sun was expressed mostly with the help of showing clay models. In some cases the children used some words. The changes in question, were changes in the spatial interrelations of the Earth and sun. The change brought something new into conceptual models leading towards the direction of scientific knowledge and that is why it is possible to say that the nature of conceptual change in these cases was additional. In one case, the revolving of the Earth around the sun indicated also the change in the examination level of the phenomenon in question.

Next, the organizing of order, continuity and regularities of seasons on the Earth level and their connection with the position of the Earth and sun on the space level will be examined. These connections and relations seemed to form the following phase in the construction of conceptual models by using PICCO. When the succession of seasons, organized on the Earth level during the use of PICCO or was organized before it, connections with the positions of the Earth and sun in space began to take shape. Connections varied from weak connections (3/11) to developed connections (2/11). In the weak connections, the movement of the Earth around the sun had been seen to be in some connection with the succession of seasons on the Earth level. In the developed connections, the connections of the Earth and sun could be seen to be in relation to the phenomena on the Earth, almost according to the current scientific knowledge of the interconnections of the Earth and sun. In both two cases, the children's conceptual models constructed, were leading towards the acquisition of scientific knowledge, and changes were additional to the existing conceptual models.

The next phase in the construction of children's conceptual models of the phenomenon by using PICCO, concerned the connections of the alternation of light and dark on Earth with the positions of the Earth and sun in space. The above-mentioned two children (2/11), who could connect, in their conceptual models, the succession of seasons on Earth with the relationship between the Earth and sun in space quite well, tried to then connect the alternation of light and dark on Earth with the position of the Earth and sun in space. These two afore-mentioned children went about the question in different ways. In one case, after the use of PICCO, the alternation of light and dark had been seen to be connected to the revolving of the Earth around the sun. In the second case, after the use of PICCO, the alternation of light and dark on Earth was seen to be connected with the turning of the Earth on the same place on Earth's orbit. In these children's models, the alternation of light and dark was not connected with the succession of seasons in the position of the Earth and sun on the space level. They were modelled separately. Conceptual change in these cases were in nature reorganization. In the first case, reorganization occurred so that old connections were replaced with new incorrect connections and in the second case, old incorrect connections were replaced with new positive connections. Changes in both cases occurred in the spatial relations between the Earth and sun.

The next phase, in the construction of conceptual models using PICCO, seemed to occur so that the alternation of light and dark and the succession of seasons on the Earth level was connected on the space level in the interconnections of the Earth and sun. This reconciliation took place in one child's (1/11) conceptual model. In his model, before the use of PICCO, the alternation of light and dark had been seen to be a result of the revolving of the Earth around the sun. In addition, the succession of seasons in the interconnections of the Earth and sun was modelled separately. In this case, conceptual change was in nature reorganization where old connections were replaced by new connections and the result was a progression towards the direction of scientific knowledge.

Changes in the interconnections of the Earth and sun also occurred in situations where, at the beginning, before the use of PICCO, the sun revolved around the Earth. In two out three of these cases, after the use of PICCO, the sun no longer revolved around the Earth. In the first case, both the sun and the Earth remained motionless. In the other case, the sun turned in one place in relation to the Earth, causing the variation of day and night and the succession of seasons on Earth. In these cases, the changes concern changes in the spatial interrelations between the Earth and sun. The old spatial interrelations between the Earth and sun break and fade away, but in the other case some incorrect relations occurred in the child's model. In the former case, conceptual change is by nature the deletion of information and in the latter case, both the deletion and addition of information.

The afore-mentioned examination has concentrated on the nature of conceptual change in children's conceptual models. Next, the summary concerning the conceptual change in the children's conceptual models of the selected natural phenomenon, in the PICCO environment is given: The point of view of the phenomenon changes, and addition, deletion and reorganization occur in conceptual models. Reorganization can be seen to further divide the replacement of existing relations with new relations, the joining together of separate relations or the finding of new relations. When examining children's conceptual models and their construction on the whole, it is possible to ascertain that the level of abstraction in children's conceptual models has increased as well. The kinds of conceptual change in this research can be recognized as are seen in Figure 3, although in the children's conceptual models the kinds of conceptual change are interwoven.

In *the taxonomy of kinds of epistemic change*, Thagard [Thagard 1992, 37] separates the following conceptual change: addition, deletion, reorganization and hierarchy redefinition. Reorganization is divided into simple and revisionary, and simple is further divided into differentiation, coalescence and decomposition. In this research, reorganization, where separate relations or parts join together, could be comparable with simple reorganization in Thagard's taxonomy. Thagard's reorganization by the principle of revisionary, can possibly be compared to reorganization in this research where the replacement of existing relations occur within new relations. Further, some features of hierarchy redefinition of Thagard's taxonomy can possibly be seen in this research as a change which is called the change of the point of view.

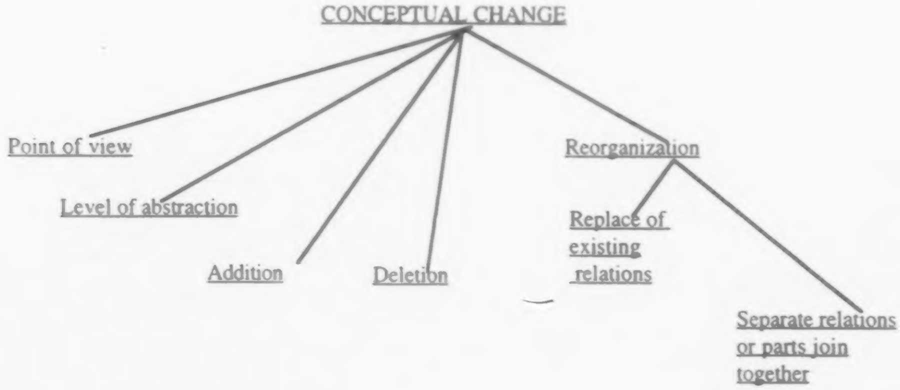

Figure 3. Kinds of conceptual change in this research

Conceptual Change Using PICCO in Relation to Conceptual Development in Astronomy

In this chapter, conceptual change in the astronomical phenomena between Vosniadou and her colleagues' research results and the present research results will be examined. From the basis of her research results, Vosniadou [Vosniadou 1991, 169] argues that children start their knowledge acquisition in astronomy by constructing an intuitive cosmological model of a flat, stationary Earth in a geocentric solar system, in which the sun and the moon move in an up/down direction and cause the day/night cycle. Eventually, this intuitive model changes to that of a spherical Earth, which rotates around its axis and revolves around the sun in a heliocentric solar system, in which the day/night cycle is caused by the axis rotation of the Earth and not by the movement of the sun and the moon. The process of restructuring intuitive knowledge is slow and is characterized by the emergence of various misconceptions of scientific explanations. [Vosniadou 1991, 1994].

When examining conceptual change in the present study, the main observation was that the development of conceptual models by children when using PICCO, occurred mainly in the direction of current scientific knowledge. Whereas, according to Vosniadou and her colleagues' research results, conceptual change in astronomical entities is seen to go through further phases where misconceptions are probable when children try to reconcile scientific knowledge with their initial models.

Although the comparison between Vosniadou and her colleagues' research results [Vosniadou and Brewer 1992, 1994] and the results of the present study has to carefully be made, because of the differences in the study of the entities and methodology, the differences in the results show that conceptual change in astronomical phenomena can proceed in a different way when children can explore the phenomenon in question, by using a computer-based simulation of that phenomenon. In this research, the scope of the construction of the children's conceptual models varied greatly but the direction in the construction proceeded towards the current scientific knowledge. In addition, the time, which the children used for exploring the phenomenon by using PICCO was on average only 60 minutes.

Abstract: This paper looks at the underlying model and interface of a Learning Guide that is part of a computer-based performance support and training system. The model uses performance data and courseware completion data to determine system confidence in a user's completion of learning objectives. Based on this confidence, the Learning Guide presents a prioritized list of relevant computer-based training components. The user is given considerable flexibility in their use of the Learning Guide and is empowered to access content that is relevant to their specific needs.

Introduction

We are working on a large project that provides computer-based performance support and training in a large financial institution [Karrer & Lukens 1997]. The primary business objective of this project is to increase customer loyalty. To achieve this goal, we have designed systems and tools that support customer advisors in effectively performing their day-to-day activities.

This project has a variety of interesting aspects in that it combines data mining, survey research, customer interaction software and interactive multimedia performance support and training. Data mining provides input that can flag customers that have some likelihood of defection. Furthermore, the rules provided by the data mining system are tied directly to suggested performance in order to provide support for dealing with the root causes of the defection. Additionally, survey research provides significant input about specific issues that have been found to be important to customers that are within the same segment. Like the results of the data mining, this information can be used to drive specific performance support suggestions.

This paper concentrates on a particular piece of this system, the Learning Guide. This guide uses sales data, customer contact data, sales goals data, planning data, and courseware completion data to drive individualized learning plans. In this system, learning plans are a prioritized list of relevant computer-based training components that are appropriate for this user. The Learning Guide is a tool that presents the learning plan to the user and provides considerable user freedom in controlling the presentation of the plan.

In this paper, I will first introduce the overall system and describe the kinds of computer-based training components provided by the system. Next, I will discuss the Learning Guide interface giving an example of its use. I will then discuss the underlying model in more detail. Finally, I will conclude with a discussion of the status of this project and future work.

PS SMART™

PS SMART™ (Performance Support: Strategic Marketing and Retention Technologies) provides computer-based performance support and training that is dynamically customized for individual needs in order to elicit employee behavior that ultimately inspires customer loyalty. The key areas of this system are tools, knowledge base, interactive presentations, simulations, on-line tests and support functions, see Figure 1.

The tools consist of a variety of applications aimed at identifying customers that should be contacted, analyzing these customers, and supporting the advisor in these activities. Customers are identified for contact for any of a variety of reasons including customer care, inconclusive prior contact, early warning indicators of loyalty gaps, cross-selling opportunities, product gap analysis, etc. Customers are analyzed by starting with an overview of the customer that includes important red flags (signals), sales opportunities, and customer segment information and drilling down through more detailed information using hypertext links. Analysis tools also help the advisor plan for customer sales contacts, providing helpful suggestions for questions to understand client needs, how to present specific products relative to the client's particular data, and to identify additional information that should be uncovered through the contact and other aspects of effective relationship building.

The organizer and reminder tools assist the advisor in scheduling appointments and is tightly integrated with the customer analysis tool so that customer data can be easily obtained with a click of the mouse. The organizer and reminder will also contain important contact and follow-up steps determined by the contact preparation and reporting tools. The sales goal and reporting tools support advisors and their sales managers in establishing and tracking sales goals over time. Several interesting pieces of data can be naturally collected by other tools such as potential customers, high-potential customers, contacts scheduled, products offered, orders fulfilled and follow-ups made. This information, coupled with the support tools, training system and standard performance benchmarks, serves as an effective basis for personal management of sales goals.

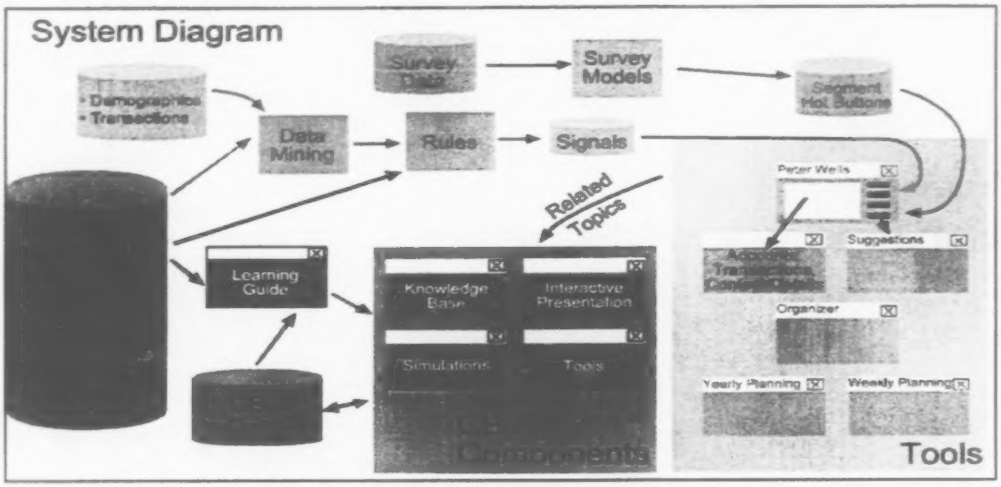

Figure 1 - PS SMART System

The knowledge base is a hypermedia reference system containing information on all aspects of the business including products, customer segments, sales styles and techniques, best practices, presentation styles, etc. It is designed for quick access of relevant information while using the tools and training. This tool is flexible and can be easily updated and expanded so that important knowledge is accessible with a click of the mouse. This tool also contains certain pages that are interactive presentations. These presentations include various user interactions or inputs to emphasize specific content points. For example, we provide a risk versus reward calculator that can show potential profit and loss given certain conditions. These presentations, coupled with video and audio segments, help to make this an effective learning vehicle.

The reality-based sales simulations provide the opportunity to play the part of an advisor throughout a sales process. Advisors can decide the best way to greet a customer, respond to a customer complaint, handle an objection, even close the sale. Users do this by making choices that drive a video-based storyline and by using tools to get customer information in the same way they are used in the real system. This virtual interaction environment is good because users can make mistakes, see the results of their decisions, and sharpen their skills before stepping into an actual branch office situation with real customers.

On-line testing exercises a broader range of knowledge than is generally possible in simulations. As in the simulations, the use of tools and best practice behavior are central to the content of the tests.

In addition to the primary tools and CBT components described above, users can also access a variety of other support functionality including communications, feedback, and search functionality. The search complements the Learning Guide, allowing the user to search for information across CBT components, i.e.,

BEST COPY AVAILABLE

simulations, tests, knowledge base and interactive presentations. Given this brief description of the system, we are now prepared to look at the Learning Guide in more detail.

Learning Guide Interface

In order to understand the Learning Guide, it is first important to recognize our main goal. This goal is to provide a list of relevant topics allowing the user to find interesting content, but not necessarily to always find the "best" topic. For example, we decided not to include the concept of prerequisites directly into the Learning Guide database. Rather, a user is able to easily navigate to prerequisite topics by clicking on a hypertext link or selecting related topics. Additionally, through the use of priorities, we can suggest prerequisites before more advanced topics. Also note that the Learning Guide is based on the assumption that there are many (thousands) of content presentation pieces. They range from half a page of hypertext to fifteen minute quizzes to thirty minute simulations. The important issue here is finding the content out of a large content space. Anyone who has used the Web knows the inadequacies of methods like searching, hypertext and hierarchies. While each of these methods exist for the user in addition to the Learning Guide, the Learning Guide serves as an important starting point for users.

The Learning Guide's interface (see Figure 2) presents the user with CBT components that are likely to be useful. When the user launches the Learning Guide, they are shown all content related to a learning objective where a performance and training gap has been identified. This gap is measured through two *confidences*: performance confidence and CBT confidence. Performance confidence is a measure of how well the user has performed in on-the-job activities. CBT confidence is how much and how well the user has performed in related CBT components. In the next section, I will discuss this model in more detail.

Figure 2 - Learning Guide Interface

Confidences and the use of the Learning Guide are best illustrated through an example. Let's consider the situation of a particular customer relationship officer, Sue. On Saturday night, a batch process runs that looks at Sue's performance data (sales, contacts, plans, etc.). During this process, one of the rules flag that her sales of stocks is well below the expected levels for someone in her role. As a result, the process looks at the associated list of learning objectives and sets the performance confidence down. In this example, we'll assume that this performance rule has two associated learning objectives: one related to understanding stocks and the other to portfolio theory. Since Sue had previously taken CBT components associated with stocks, the total confidence (performance confidence + CBT confidence) for the stock learning objective is considerably higher than that for portfolio theory.

The next time that Sue logs onto the system, runs the Learning Guide, and requests recalculation, the system runs through the learning objectives finding any whose total confidence is below the threshold for her role as a customer relationship officer. In this case, the portfolio theory objective is identified as the lowest. The Learning Guide then displays the list of content items that relate to portfolio theory: a test on portfolio

BEST COPY AVAILABLE

theory, an interactive presentation, and several knowledge base topics. Sue is able to select one of these topics and display it. If she selects a knowledge base topic, the result of that visit is that the CBT confidence goes up for portfolio theory (along with other related learning objectives) by some preset amount that we call a *factor*. If she takes the test and does well on the questions related to portfolio theory, again her CBT confidence will go up by some factor. If she looks at the Learning Guide again, the topics that she has gone to will still appear, but they will be marked as visited. If she requests recalculation, then the portfolio theory topics will have a higher total confidence and will have been removed from the Learning Guide list.

As stated previously, user control is central to the design of the Learning Guide interface. Some of the control is providing a longer list of finer grain CBT components and allowing the user to select from this list of "probably" relevant topics. The user is also given control through preference settings. The user can change confidence level thresholds across a variety of categories of learning objectives including system use, product knowledge, sales process and sales techniques. This allows the user to "turn off" general topics that they do not want to focus on. The user can also use the Learning Guide to select other job titles that they want to train for. The Learning Guide marks topics that the user has visited recently, and the user can set "not interesting flag" on topics that they want to erase from the list. This topic will not be shown again until some specified period has expired or the user asks to clear these flags. The user can sort the list by type, e.g., simulations, tests, knowledge base, etc. This allows the user to easily "test out" of some learning objectives. Other users can select content according to presentation style. Overall, these controls allow the user to determine the best use of the Learning Guide.

Learning Guide Model

The Learning Guide model is a database and associated rules that determine what information should be relevant to that user. This model is shown in Figure 3 which depicts the tables for the previous example. The tables shown in Figure 3 are obviously not the real tables, but rather are presented to give a flavor of the model.

The starting points for the Learning Guide model are a list of learning objectives, information about content and information about roles as they relate to learning objectives. The learning objectives are detailed knowledge and performance requirements relating to sales process and sales techniques, products, planning, company information, and use of the system. Associated with each learning objective is a list of knowledge base topics, interactive presentations, tests, and simulations. The content of these related components help the user to achieve that learning objective. Also associated with each content item is a confidence factor that indicates how much CBT confidence should go up by completing that component.

Role information indicates default thresholds and priority for each learning objective relative to the user's job title (role). Users can select other job titles they are interested in, thus increasing the priority of some learning objectives. For this environment we found using job titles worked fine. In other corporate environments, users with the same title do very different work. In that case, job title would have to give way to more detailed job functions. However, the same basic approach of combining several job functions should work.

Each user in the system has a list of confidences associated with each learning objective. As stated previously, total confidence associated with a learning objective measures how confident the system is that the user has achieved that objective. As stated earlier, performance confidence is a measurement of system confidence based on job performance. Performance confidence is fully calculated once a week based on updates to performance data. CBT confidence is based on taking and doing well in related training components. Initially, CBT confidence is based on number of years experience at this company in this job and in other similar jobs, amount of system experience, and results of a preliminary on-line questionnaire. CBT confidence changes over time based on visiting knowledge base topics or interactive presentations related to the learning objective. They go up or down based on correct or incorrect answers in tests and simulations.

The more interesting aspect of this approach is the use of actual performance data in calculating performance confidences. The calculation of performance confidence looks at performance at several levels: strategic planning, making contact, contact effectiveness, and sales results. At the strategic level, individual users are provided with tools for planning customer contact over the next year and for the next week. Using a simple rule that compares the total number of planned contacts of various types against expected numbers allows us to flag performance gaps in strategic planning.

After strategic planning, the next step is to make the contacts that were planned. Using information about the number of planned contacts and the number of actual contacts, we can calculate confidence based on contact percentage. If the contact percentage falls below a threshold, we lower the performance confidence related to those learning objectives.

Figure 3 - Learning Guide Model

Assuming that the user is making sufficient contacts, the next check is to ensure the effectiveness of the contact. Because not all contacts are sales attempts and even not all sales attempts should result in immediate sales, it is important to closely categorize the type of contact. Many contacts are simply to increase customer knowledge, to handle customer care or to do other customer service free of any direct sales. Because we have categorized contacts into a variety of types, we can not only make sure that parts of the sales process like customer care are understood, we can also make sure that our system focuses the learning model on just the relevant sales opportunities. Specifically, the system looks for situations where a contact was planned with the intent to offer a product, the contact occurred, and the offer was not made or the offer was made and the product was turned down. On a case-by-case basis, these individual contacts can be explained away quite easily. However, a pattern often emerges that suggest some performance gap. For example, if contact is made, but the product is not offered (some other issue was discussed instead) and this happens repeatedly, then performance confidence gradually wanes in the objectives of turning contacts into sales opportunities. Thus, over time the system will begin to identify performance gaps, but at the same time the system does not necessarily focus on any one individual case.

Finally, we can use the benchmark of sales data. This data tells us how the advisor has done in selling specific products and product categories. We also have an expected sales level for each product category. Thus, when a user's sales in any particular product category falls below the expected level by some threshold, we lower the confidence of learning objectives related to that product. We also look at total sales; this can be a determinant of performance gaps in more general sales techniques such as needs analysis. Thus, even though the user may not fall below the threshold on any one product, the user may fall below the threshold on overall sales.

Conclusion, Related & Future Work

PS SMART™ is currently a prototype, and we are working on the development of the pilot version. While we will achieve more insight into the utility of the Learning Guide as it is used more across ever larger content, preliminary results are encouraging. Because the Learning Guide is limited in its goals and because there are other navigation (hypertext, search, and hierarchies), it appears to fill the important function of finding interesting starting content in large content spaces. It seems to avoid the problem often found in searching on the Web, namely where to start.

This approach and the goals of the Learning Guide are considerably less ambitious than Intelligent Tutoring Systems (ITS) which focus on emulating a human teacher's ability to plan a students activities based on domain knowledge, instructional models and student models. The Learning Guide does incorporate a student model in terms of content seen and performance both in instructional activities and on-the-job. However, the content presentation is more like that of standard computer-based training and hypermedia. Content presentation is not dynamically modified (as in ITS), rather it is only dynamically indicated what might be appropriate. In our environment, a high degree of user control was considered essential, leading the overall goal of guidance.

This approach is similar to the Guided Discovery System [Elsom-Cook 1990]. In this system, the user is guided to appropriate learning activities based on a network of learning objectives and their performance in learning activities. Many of the same approaches to deriving confidence were used in the Learning Guide, but the Learning Guide extends the confidence measures based on actual performance. Again, this is important in environments where a central concern of users is to "avoid content they already know." However, our initial findings suggest that further use of a model of content similar to Elsom-Cook's learning objective network may improve our guidance considerably.

While the basic structure of the Learning Guide has been designed and preliminary indications suggest it will be effective, we will gain significant insight into its usefulness during the pilot. During the pilot we will collect data to drive analysis of the effectiveness of the training. In fact, we should be able to measure all four learning evaluation levels as defined by Kirkpatrick [Kirkpatrick 1978]. During deployment, we plan to closely monitor situations where CBT confidence is high and performance confidence is low as this will suggest gaps in effectiveness of the training. We plan to also use data mining techniques to evaluate the correlation between system use and organizational outcomes including economic impact questions [Godkewitsch 1987]. Ultimately, we will try to tie together data at all four learning evaluation levels to improve training and further direct employee performance and learning strategies.

Overall, the Learning Guide model provides the basis for identifying topics that are likely to be relevant to users based on actual performance data. The Learning Guide interface provides quick, easy access to the topics and considerable user control in defining what is interesting to them. Coupled with development of architectures and engines [Karrer 1996], this serves as a cornerstone of the overall training and performance support approach within PS SMART™. Ultimately, it provides the basis of generating needed behavioral changes required to increase customer loyalty.

A Virtual Laboratory for Beginning Scientists/Engineers

Michael Karweit
Dept. Chemical Engineering
Johns Hopkins University
Baltimore, MD 21218
mjk@jhu.edu

Abstract: In this paper we report on the development of a set of "virtual" laboratory experiments, i.e., computer simulations, for beginning science/engineering students. Written in JAVA for use over the Internet, the simulations were designed to expose students to problems for which single, deterministic, "textbook" solutions do not exist. The experiments—ranging from the determination of the topology of hidden surfaces to the design of digital logic circuits—involve design, measurement, and estimation, and give students a taste of the range of problems found in engineering.

This virtual laboratory exists at **http://www.jhu.edu/~virtlab**

Overview

In this work we focus on two questions related to science/engineering education:

- An educational question: Could simulated experiments be developed to provide laboratory insight for students not having access to a physical laboratory?
- A practical question: Could interactive experiments be written in JAVA so that they might be delivered through the Internet?

The answer to both questions appears to be YES.

Here we report on the development of a JAVA-written, web-based "virtual laboratory" of interactive experiments designed to expose beginning science/engineering students to scientific inquiry and problem solving. These simulations will be organized into a freshman-level course, "What is Engineering?", to expose students to multi-parameter decision-making, approximation, parameter estimation, and data evaluation in a variety of engineering disciplines. Experiments include: inferring hidden surfaces, calculating heat transfer coefficients from holographic interferograms, programming robotic arms, and designing digital logic circuits.

At present, these modules are successfully replacing laboratory experiments in several existing university courses. Access is via the Internet.

This Virtual Laboratory can be reached at **www.jhu.edu/~virtlab**.

Introduction

Engineering (and science) curricula, at least up to the junior year in college, consist almost entirely of mathematics, physics, and chemistry. Although these subjects are certainly the analytical building blocks for the discipline, they do not teach students that engineering is an art that requires ingenuity, design, and creative problem-solving skills.

Throughout secondary school and continuing through the first few years of college, students study material by individual subject, one chapter at a time. They are then presented with problems for which there is typically one approach for solution, i.e., one equation found earlier in the chapter, and one explicit answer. In fact, beginning students are never given the opportunity to develop skills to deal with problems that are not simply "plug and chug". Only in junior or senior laboratory design courses do students begin to think about problems which require innovative approaches for solution. A recurring comment among professional engineers is that students need to learn to apply their analytical skills; and this can be accomplished by students taking more laboratory courses earlier in their academic careers.

There is a related issue. Students at four-year colleges and universities are typically offered a wide variety of science/engineering courses. Resources at these institutions include highly-specialized faculty and well-equipped science laboratories. But engineering students studying part time or students attending community-oriented two-year colleges will not necessarily have access to comparable courses, facilities, and expertise. For these students, opportunities to develop sophisticated engineering skills are often limited. Might there be a way to increase their exposure to laboratory-related problems without great expense?

The essence of engineering is learning how to think. It does not consist of carrying out calculations of well-posed, simplified problems. It is the process of translating real-world problems into ones which are amenable to solution. It is determining what types of solutions are needed. It is devising approaches that will yield adequate solutions. These are objectives to which students should be exposed at the beginning of their education, not at the end.

How does one teach students how to think? By exposing them to assignments that are open-ended--those that require hands-on exploration, those that are prone to measurement error, those that are too complex to be solved directly with simple analytical tools, those that require multi-parameter decision making. These are elements that are most naturally incorporated into task-solving laboratory courses.

A Virtual Solution

We are addressing these issues by developing a freshman-level, virtual-laboratory course, "Measurement, Experimentation, and Design". This course is being produced on a multimedia/WWW platform, so that its ideas and goals can reach beyond the campus of a research university. The heart of this course--what we are focusing on in this paper--is a Virtual Laboratory, a set of open-ended, thought-provoking experiments written in the programming language JAVA.

That a multimedia approach might be suitable for such a course requires some elaboration. First, whereas multimedia has always been capable of presenting audio, visual, and textual material, it has not provided the user with the ability to perform actions that alter the outcome or the data; i.e., one could never conduct a simulated experiment using conventional multimedia. With JAVA, however, it is now possible to create virtual experiments in which the user determines the course of execution. Second, since JAVA exists as a language within most Web browsers, users on all computer platforms have comparable access. Third, if one produces multimedia information trees using HTML and JAVA, then course material may be made available on individual CD-ROM or on Web servers without modification. What this means, is that course material may be offered locally or at a distance with equal ease.

Collective problem solving is also possible using this technology. If a virtual laboratory course were offered via the WWW, a central Web server could establish student groups, the members of which could interact via e-mail. Group assignments could be electronically assembled and sent to the central server for evaluation by a distant instructor. Existing software, e.g., Web Educational Support Tools (WEST), could be used for course administration over the WWW.

The Virtual Laboratory

We describe here five of the completed experiments in the Virtual Laboratory. Corresponding to each of these descriptions are Figures 1—5 which illustrate what is presented to students as they perform each experiment.

1) **Logic circuits**: Create circuits from AND, NOT, and NOR gates to effect logical outputs. Here, students assemble virtual components to produce desired logical properties. Circuits can be tested by assigning proper inputs and noting results. Assignments vary from simple three-input AND gates to multi-digit binary adders to robotic control circuitry.

2) **Drilling for oil**: Suppose it were necessary to determine the curvature and orientation of a stratum of oil-bearing shale. The depth at which this stratum lies can be only obtained by drilling a hole until it is reached, and then measuring the depth of the hole. Given a limited number of possible geometries, the problem is to determine the characteristics of this hidden surface at minimum cost. Cost factors include number of drill holes, terrain, and depth.

3) **Robotic arm control**: Consider a two segment robotic arm whose tip is required to move through a sequence of specified trajectories. Control is effected by prescribing the rates of change of the angles between the links; i.e., by prescribing the angular positions of stepper motors. Assignments include: Prescribe a set of commands that will cause the arm to traverse its range along the x-axis at a fixed elevation y to within a specified tolerance; deduce the range of action of the arm; prescribe a set of commands that will take the arm through its trajectory at constant speed.

4) **Heat transfer in a duct**: An experiment consisting of air blowing over a heated, ribbed surface is described. Motion holographic interferograms taken during the running of the "real" experiment are presented. The objective is to make measurements from these interferograms and deduce the Nusselt number--a measure of the heat transfer. The problem is to estimate temperature gradients based on visual data.

5) **Bridge designer**: This is a design platform for developing simple truss bridges. By creating nodes, connecting them with members, and adding loads, students can explore bridge designs and examine the compression or tensile stress experienced by every element of the structure. This module is used in conjunction with a project to design and build a load-bearing model bridge.

These modules are currently being used successfully as supplemental or replacement experiments in several existing engineering courses. Response has been very positive. Students find the problems interesting and challenging, and, since the "laboratory" resides on the WWW, students are not tied to performing the experiments in a designated time slot at a specified place. There are benefits for faculty and administration, too. Problems with scheduling, maintaining, and staffing laboratories are eliminated. Laboratory costs are drastically reduced.

Coupled with MPEG video lectures and supporting materials, these virtual experiments will be integrated into a complete multimedia, science/engineering laboratory course that can be delivered asynchronously anywhere.

Virtual laboratories are not a panacea. In spite of the fact that they can offer highly-interactive experiments, they cannot duplicate the experiences obtained in handling real apparatus. But, when laboratories focus on design or problem-solving and when lessons are not dependent on physical equipment, the educational differences between *real* and *simulated* narrow to the point where virtual experiments become very viable options.

Real Problems

Creating virtual experiments is not for the faint-hearted. JAVA, WWW browsers, and client-server communication software are new technologies. Lack of documentation, un-implemented standards, browser inconsistencies, and constantly revised software make the development of simulated experiments a daunting task. We presume that, as these technologies mature, the majority of these problems will disappear and virtual laboratory and course development will become more practical.

Conclusion

Multimedia-delivered courses are not new. But multimedia-delivered courses that offer interactive laboratory work are. The present effort shows not only that such courses are possible, but also that they can be effective. And they appear to have the potential to extend the opportunity for science/engineering education well beyond the walls of the university campus.

Discrimination Learning: Coupling Categorization and Classification
Preliminary Research Report

Ernie Chang[1], Larry Katz[2], Mark Wylie[3]

[1] - Axia Multimedia Corporation
[2] - Faculty of Kinesiology, University of Calgary
[3] - Department of Educational Psychology, The University of Calgary

Introduction

A concept such as diabetes, or an object such as an F-18 fighter jet, can be represented as a category with a set of properties. In accordance with Rosch (1978), a category is a number of things considered equivalent, and has properties serving to distinguish it from other categories that are similar to it. Whether we deal with categories that are fundamentally perceptual and sensory like speech and color processing (Harnad 1987), or with abstract higher-order categories such as the PG ratings of movies, there exists both a *declarative* aspect and a *procedural* aspect to categorization.

Declarative is defined as all the prototype and boundary characteristics that define a category, and *procedural* is defined as the process of identifying an object (with one or more characteristics), as a member of that category, and not some other similar category. To learn a category one must deal with both aspects: learning the characteristics of a specific category, such as what is an F-18, so that from its identification a whole set of associated characteristics can be inferred; and also learning to identify the category that best fits a particular set of characteristics. These two aspects are referred to in this paper as *categorical* and *classification* learning.

Most approaches to the learning of categories are based on a didactic approach: linear and depth-oriented presentation of information, focusing on the detailed properties of the category in question. For example, we learn about diabetes by reading, or by being told information about diabetes as a disease. However, this model building does not necessarily create the ability to classify a set of symptoms (characteristics) as diabetes, because classification requires a breadth-oriented knowledge of how similar categories differ one from another.

In general, the characteristics of categories are taught and learned separately from the ability to classify things into their appropriate categories. This is not ideal, because the two kinds of knowledge are clearly inter-related. Knowing what is in a model (diabetes) is of limited value if one cannot diagnose diabetes; to diagnose diabetes, it is necessary to have an in-depth knowledge of diabetes.

The most common method for acquiring classification knowledge is through experience, rather than by establishing formal pragmatics for learning classification. In part, this is because of the difficulty of obtaining sufficient cases in an inquiry-based format with which one can practice classification; and, in part, due to the difficulty of providing appropriate feedback to the learner, in the form of inter-category distinctions.

Finally, if authentic tasks and situated context are critical to learning (Brown 89, Spiro 88), then providing an environment of appropriate context and near-real tasks in classification learning (other than in real training, or computer simulations) is essential. However, this has always been a challenge.

The summary of research on combat vehicle identification training for the period 1980-85 at Fort Hood, Texas (Smith 89) is indicative of the approach taken using manual techniques. Generally, slides and flash-card presentations were used. The results of training with five vehicles were good, but fell to an average of 30-35% when training was performed with 30 vehicles, which was accomplished with six modules over about 240 minutes in total time. Side-by-side comparison of similar vehicles, with features pointed out by instructors, gave remediation a 56% improvement. Attempts to find correlations of performance to student-intrinsic factors did not produce significant results.

Axia Multimedia Corporation has brought a highly interactive multimedia, student-centered approach (Chang 1993, 1994) to the learning of categories and their classification. Its Discrimination Learning engine provides authentic identification tasks, multiple representations of objects for comparison, uses questions to set contexts, and uses mis-identifications as opportunities for learning classification as well as categories.

This study, using the above approach, was undertaken as the first of a number of planned investigations into the nature of classification knowledge, and specifically, into the effectiveness and efficiency of learning both categorical knowledge and classification knowledge in a coupled way, so that one motivates, drives and informs the other.

Background

Axia Multimedia Corporation has developed a unique and patented approach to learning, called Discrimination Learning, which supports the incremental learning of classification skills and categorical knowledge (US Patent 5,449,293).

In terms of broad architecture, the Discrimination Learning Engine supports multi-dimensional comparison of a set of Items by using side-by-side windows, with a set of Aspect buttons between them. These Aspects are multiple representations of the Item set, while multiple Instances of an Item-Aspect, with secondary voice-over audio, labels and text (see Figure 1), provide levels of detail which are also a powerful scaffolding mechanism.

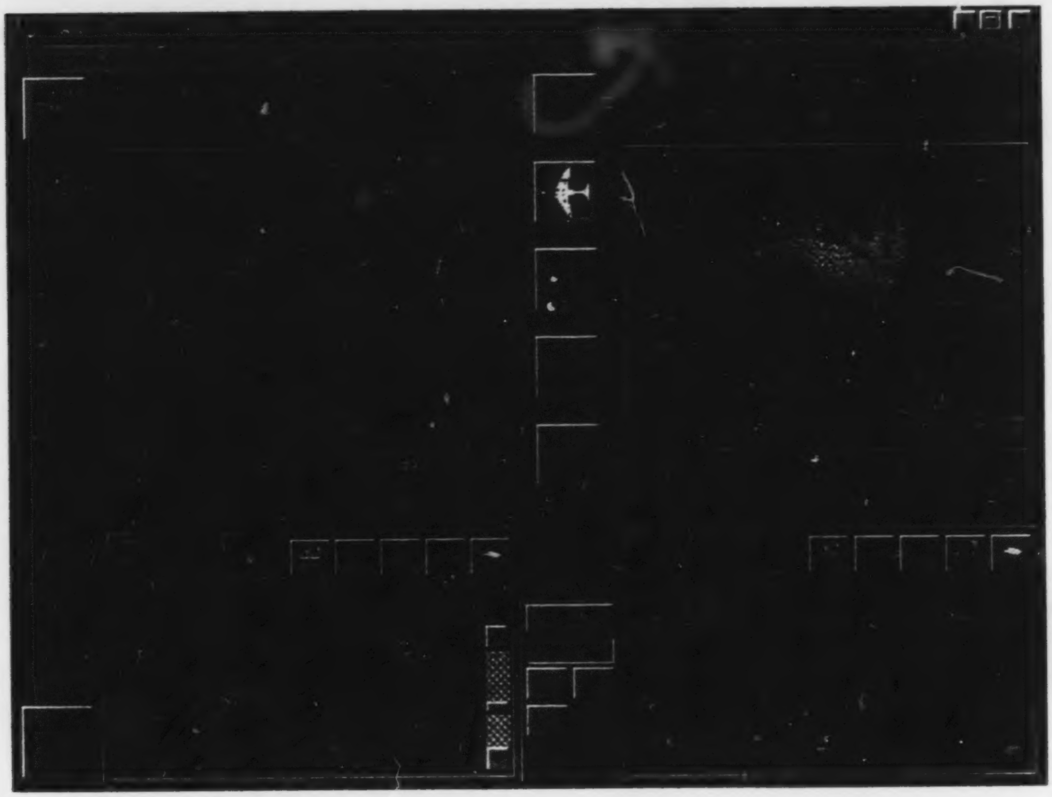

Figure 1. Discrimination Learning Engine - Know Your Combat Jets

Using Reference Mode, a student can select the same Item in the left and right windows, and compare different Aspects (representations), or different Items in each window, comparing them in the same representation, with or without labels or other detail.

Challenge Mode provides an inquiry-driven interaction in which the student is asked to identify the image, using the list of Items for answer selection, or typing in the answer. If a mis-identification is made, the system shows the user the Guess item, using the same representation as the Target (image to be identified). This allows the learner to compare them using labels, other Aspects, or attempt another identification.

To increase the authenticity of the task, the student can select a subset of Items, and can use the timer to limit the duration of the image on-screen. At any time, the student can click on the Answer button rather than making a Guess.

Incremental learning is a mechanism through which a student can choose the size-of-learning set with which to work, implementing a divide-and-conquer strategy. It is simpler to discriminate among three items than thirty.

BEST COPY AVAILABLE

This research study was established with three broad goals in mind: first, the effectiveness of coupling categorical and classification learning compared to more standard approaches; second, the gaining of some insight into the response of students to open interface systems, which react only to the student's actions; and third, the gaining of insight into the extent to which students use different tool capabilities for learning.

Method

In this study, 56 military personnel were selected from various military units in Southern Alberta. The objective was for the soldiers to use the Axia multimedia product *Know Your Combat Jets* to study differences in learning effectiveness based on the theoretical framework presented earlier. Each soldier had up to 90 minutes to learn to identify 40 different fighter jets. The soldiers were provided with images of 40 selected jets which may realistically have been encountered while on a mission to Bosnia.

All the soldiers were first asked to fill out a personality inventory. They were then given standard instructions on the multimedia system's capabilities. The multimedia program had numerous components and the study was designed to assess different aspects of the Discrimination Learning engine. Soldiers were randomly assigned to one of three groups.

The first "*Reference Learning*" group, studied 40 fighter jets by their characteristics only (model building), with no opportunity to do classification until the test. The second, "*Challenge Q/A*" group, was allowed to use Challenge Mode, and was asked by the system to identify a fighter jet selected at random, but participants could only obtain the correct answer. This corresponded to classification only. The third, "*Comparative Feedback*" group, could use Challenge Mode, but had the added ability to submit a guess, which produced upon mis-identification a comparison feedback, showing the guessed aircraft in a side-by-side window next to the "target". This corresponded to the coupled categorical - classification learning group.

After the learning session, the soldiers were administered a test of their knowledge. The test bank consisted of a mixture of 40 photographic and silhouette images of the target jets, some drawn from the learning set and some from new sources. Each soldier's computer screen performance was videotaped for the duration of the learning session.

Results

The raw data consists of three sets of information: the answers provided by each soldier on the 40 item Jet Recognition Test, results of the personality inventory, and the video of the soldier's learning interactions, as seen from video tapes of the screens. Each question on the Jet Recognition Test required a typed answer, therefore, a scoring system was needed to deal with spelling mistakes and incomplete names.

To date, the 40 item Jet Recognition Test data has been analyzed and the tapes have been annotated in detail. However, neither the personality inventory nor the tapes have been analysed so only the test data and some preliminary observations from the tapes are discussed in this paper.

Jet Recognition Test Results

Table 1 shows the means and standard deviations of the three groups on performance in the Jet Recognition Test. As can be seen from the data, the "*Comparative Feedback*" group performed the best, although the overall average of 8.34 is quite low relative to a perfect score of 40.

Group	Count	Mean	Standard Deviation
Reference Learning	19	8.42	4.10
Challenge Q/A	18	6.28	4.56
Comparative Feedback	19	10.21	4.64
Total	56	8.34	4.64

Table 1

Means and Standard Deviations of the Model, Classification and Classification Category groups on performance in the Jet Recognition Test.

As can be seen in Table 2, a standard one way analysis of variance on the Jet Recognition Test shows that there is a significant difference in performance between the three groups (df = 2,53; F = 3.64; p < .05).

Source	D.F.	Sum of Squares	Mean Squares	F-Ratio	F-probability
Between Groups	2	143.15	71.58	3.64	.033
Within Groups	53	1043.40	19.69		
		1186.55			

Table 2

Analysis of Variance for Model, Classification and Classification/Category groups on performance in Jet Recognition Test

A subsequent *post hoc* Scheffe test showed that the "*Comparative Feedback*" group performed significantly better than the other groups. While this represents the traditional method of analyzing the data, a more visual representation of the data can be seen in Figure 2.

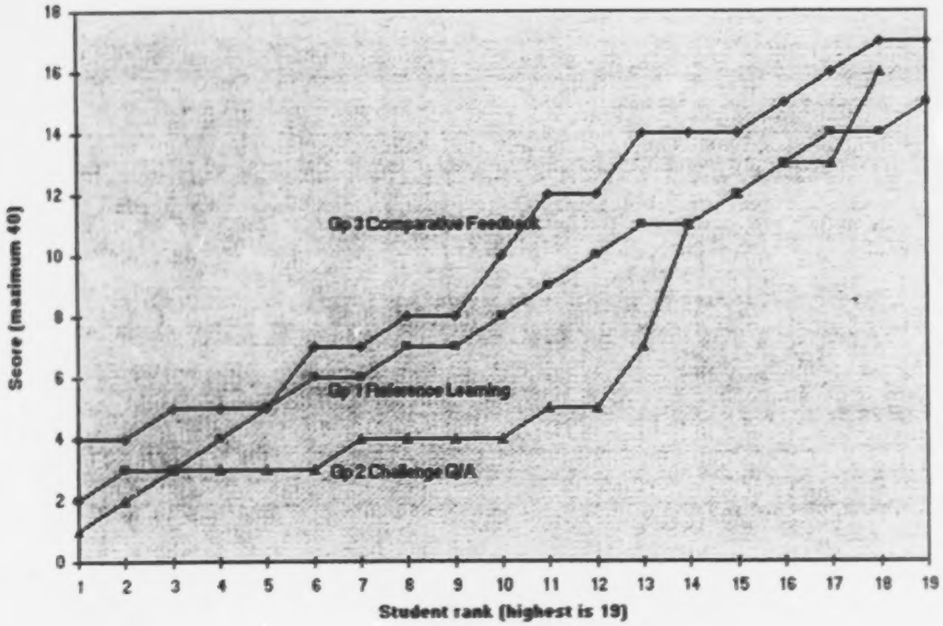

Figure 2. Comparison of Three Learning Strategies Using KYCJ

As can be seen in Figure 2, soldiers are listed by group from lowest to highest performer. If one assumes random assignment, then ability should range in each group from low to high performers irrespective of treatment. If there is a significant difference between groups, then there should be a consistent, parallel separation between the slopes of the groups. This new method of representing the data gives the researcher a much clearer understanding of the data and is highly recommended.

Preliminary Videotape analysis

From the videotapes, it appeared that most soldiers finished the learning session before the 90 minute time limit. Only a few soldiers used the levels-of-detail features of the program such as the labelling component which allows a learner to distinguish among characteristics of an aircraft. None of the learners used a divide-and-conquer strategy of incremental learning, nor did anyone use the Timer, to improve expertise. Most soldiers did not use multiple representations; that is, study an aircraft in photos and technical drawings and silhouettes, nor did the "*Comparative Feedback*" group follow-up a mis-identification by exploring the similarity space around the Target image.

Discussion

Jet Recognition Test Results

As can be seen from the results, Jet Recognition Test results were quite low, averaging 8.34 out of 40, or 21%, with a high score of 26%. These results were obtained from one learning session, with a maximum of 90 minutes in which to learn 40 combat jets. These results are consistent with the Combat Vehicles Identification studies (Smith 85), which ranged from 30% to 35% where the task was to learn 30 vehicles over six session involving 240 minutes. Despite the overall low scores, there were definite group differences.

The "*Comparative Feedback*" group scored significantly higher than the other two groups, with an average of 10.21 of 40, compared to 6.28 out of 40 for the "*Challenge Q/A*" group, which represents a difference of 63%. The visual analysis of the data as seen in Figure 2 shows remarkable consistency over the entire range of ability levels, as illustrated by the essentially parallel lines for "*Comparative Feedback*" relative to the other groups.

Although the *post hoc* Sheffe test did not show a statistical significance difference between the "*Reference Learning*" group and the "*Challenge Q/A*" group, the visual analysis and the data suggest that the "*Reference Learning*" group may have performed better than the "*Challenge Q/A*" group and the researchers are currently undertaking another study to clarify this issue.

From the results, it would appear that Comparative Feedback is a much more powerful learning method than either Reference Learning or using test and right answer feedback. If these differences are real, then there are major implications for the standard test and right answer feedback models currently used in most educational situations.

A possible explanation for this outcome is that students when answering an identification question may postulate that the observed features belong to a category representing the answer, and make cognitive commitments in that respect (i.e. the category chosen as the answer is the focus of attention). Upon being told that the answer is wrong, and shown the right answer, significant work must take place in order to shift the focus of attention to the right answer, and to fit the appropriate features to the new category.

The "*Comparative Feedback*" group, by contrast, is shown an image corresponding to the mistaken answer, with all its features, so that learners can first revise the internal map of the features from the incorrectly chosen category which was the focus of attention. Then, the learners can construct the between-category knowledge of differences, thereby improving knowledge on both objects.

Preliminary Video Analysis

While the soldiers were allowed 90 minutes to complete the project, only a few actually used the full amount of time. In view of the overall low scores, there appears to be a remarkable discrepancy between the results and the learners decision to test without taking advantage of the full training time.

In addition, it was clear that few of the students used the scaffolding mechanisms present in the Discrimination Learning Engine, all of which were demonstrated at the beginning of the training session. These mechanisms include labels, text, multiple representations, comparison, incremental learning, and the image presentation timer.

Assuming that motivation was present to learn, and that the interactive learning environment was itself motivating, it would appear that soldiers in the research study did not appreciate or understand the value of the interactive learning tools and therefore they did not use those tools to improve performance. For example, displaying the labels tool would have unequivocally shown that the EA6-B Prowler is different from an A-6 because of the radar bulge on the top of the tail. Since none of the soldiers utilized this tool, they confused the two aircraft on the test. If they knew from the introduction that labels gave information about the distinctive features of an aircraft one wonders why they did not use the tool. Moreover, soldiers did not accurately evaluate their level of acquired knowledge relative to the test requirements, effectively declaring themselves ready to test when they were actually unprepared.

In summary, there are three findings from this preliminary study which need further analysis and replication.

1. Coupling categorical and classification learning is more effective than memorization, or being given the right answer in quiz mode,

2. Just giving the right answer to a wrong response in a discrimination learning task may actually impede learning, and

3. Learners do not use tools which could enhance learning and do not take full advantage of learning time possibly because they overestimate their knowledge.

Given the relatively poor results, even for the "*Comparative Feedback*" group and the non-optimal use of available tools, the researchers are conducting a follow-up study with Military Cadets. In the follow-up study, more explicit instructions and strategies on the use of scaffolding tools will be incorporated into the design.

Multimedia: Promises to Keep and Miles to Go...

Larry Katz
Faculty of Kinesiology
The University of Calgary, Canada
katz@acs.ucalgary.ca

Abstract
The vision of multimedia, technological innovation, learning and entertainment, evokes an intriguing and exhilarating blend of possibilities in an educational realm with promises unfulfilled. Such a relationship has great potential. As technology moves toward integrating telephone, television and desktop computing, and as our students develop more sophistication with the use of technology, we have to start questioning our role as educators. This paper attempts to "eschew obfuscation" and examine the evolution of multimedia as a valuable learning and information resource--its potential, and its peril.

In The Beginning...

Over the last twenty years, technology has evolved faster than anyone could have predicted. Every year since 1978, I have shown my students a picture of two children walking toward their school only to be greeted by a 'Robot' teacher. One child says to the other "I have a feeling things are going to be different this year". Amusing, yet, the vast majority of teachers, schools and universities throughout the world are using the same methods of teaching that have been employed for over one hundred years. An argument could be made that slides and other audiovisual aids make a difference, but these "technological innovations" are essentially just being integrated into the old way of doing things.

The world wide web is being used, even by the more adventuresome of our colleagues, simply as another method of presenting lecture notes. This Piagetian paradigm of "assimilation" involves taking new things and attempting to fit them into existing models. Posting lecture notes on the world wide web for students to read is not so very different from photocopying lecture notes for distribution in class. Although posting on the web may save paper (unless the notes are printed off) and is effective for updating information, it is a major disadvantage for the socioeconomically challenged students, and ties the student to a computer monitor.

The very first computer-assisted instruction programs consisted of converting math lectures for presentation on a computer screen, with electronic page turning. At the end of the computerized lesson a drill and practice session would be introduced using the same type of questions usually located at the end of a chapter in the standard mathematics textbook. A major advantage of the computer was the immediate feedback to the learner. The computer could quite easily tell you to "try again", with infinite patience, perceived dedication, and an occasional "please concentrate' or "well done".

Again, this is an example of using technology to do things the same way as before only perhaps a little faster, better, easier, and in a more accessible manner. This is far from using the full the potential of technology--that would require completely different models for teaching and learning.

In the early years of computer systems the speed was such that you could go out for a coffee while a program was loading. It is interesting that in using the world wide web, we find ourselves waiting again. Have we really progressed? Now we use the computer to present graphics and audio/visual information and call it multimedia, but the video quality on our computer screens is substandard to that of television which has been available for over 40 years.

Multimedia, not...

Is it not intriguing that our children think the painter of the Cistine Chapel is a Ninja Turtle, or that the most widely recognized personality amongst North American children is the plumber, Mario--a flat, undeveloped animation character. At least our generation in its youth identified with a wacky mouse that was fully endowed with a 'wired', multi-faceted personality--the immortal Mickey. Neil Postman in his book, "Amusing Ourselves to Death" points out that mankind has an insatiable appetite for distractions. Certainly, technological toys and gadgets will feed that appetite, but we run the risk of becoming a trivial and shallow society.

Multimedia is not just the integration of the various media (audio, video, graphics, slides, animation, text and technology), but also the interaction of technology and people. The most inexpensive and sophisticated human computer interfaces available today are aimed at the video games market and are being purchased for children. High technology, interfaces, virtual reality head-sets and power-pads are built at the cost of millions of dollars and mass marketed by companies such as Nintendo^{TM}, who have "captured your dollars and enslaved your children" (Sheff, 1993).

Multimedia is still in its infancy and already there are thousands of titles, most of which do not return profits to their developers, Miller (1994). Many multimedia titles remain unopened after purchase. Analysis of the most popular and widely distributed titles shows computer games as the leading category (Sheff, 1993)-- and not just for children.

Many technology users spend huge amounts of time surfing the "web" and yet we still do not have a clear picture of why this is so. The world wide web has amazing potential and is growing faster than any other single product in the history of mankind. It is a place where, at long last, every man, woman and child has the opportunity to realise their promised "15 minutes of fame". By posting your own web site, you can have recognition world wide, no matter how obscure your ideas may be. Add colour, video and sound, call it multimedia and who knows what you can achieve?

The Issues...

Ashleigh Brilliant suggests that there has been an alarming increase in the number of things of about which we know nothing. Perhaps, multimedia and the world wide web provide people with easy access to answers to questions that arise at the most inopportune times. But, how do we know that the answers they find are correct? How does one collect, analyze, verify and integrate new knowledge into existing systems? How do educators help their students to create and disseminate new ideas and knowledge? How does one reexamine the way we do things in the light of new technologies. It should come as no surprise that computers can play chess better than the best human chess player and win the game and yet humans continue to play chess with one another. With multimedia, will computers teach better than the best human teacher and replace them? Is that the right question to be asking? Humans create the technology and challenge it, but still require human interaction to excite the emotions and enhance the quality of life.

The traditional system of education deals with learning from a linear perspective (lectures, textbooks, assignments, tests and due dates). Howard Gardner (1983) addressed the issue of multiple intelligences and suggests that there are at least seven different intelligences, most of which have been neglected in our test oriented society. Multimedia, in the broadest sense of the word, can address a multitude of learning styles and rework the system so that students can use existing knowledge to create new knowledge, and move from passive recipients of information to active developers. Essentially, students can become active participants in planning and creating their own learning opportunities.

Despite the fact that technology provides us with amazing opportunities and potential, in the field of education few people are integrating technology effectively into their teaching and learning. Perhaps it is a combination of ignorance, fear, lack of time, or a resistance to change, but it is clear that the next generation of students will arrive at universities with experience and expectations which will drive change or which will result in the obliteration of the institutions as we know them today.

One of my students tells the story of her eight year old son who woke up at two in the morning and discovered his mother in the study working on a multimedia project. He sat watching her in deep fascination for a prolonged period and then said to her: "How come you get to do all this interesting stuff and I have to go to school?"

It was stated earlier that most educational facilities have yet to incorporate computer technology into their existing systems. Perhaps it should be asked if technology should be changed to fit existing systems, or is it time to change existing systems to fit into the new communication era?

Rethinking the Implementation of Distance Education Programs

David A. Keast, Special Sessions, 4-107A Education North, University of Alberta, Edmonton, Alberta, Canada, T6G 2G5. E-mail: David.Keast@UAlberta.CA

Abstract: In early September, 1995, three institutions in Alberta, Canada, embarked on a new partnership in offering a selected number of introductory Bachelor of Arts courses in remote northwestern regions of the province. The primary mode of delivery was multi-point videoconferencing with all courses delivered from the University of Alberta campus. Slightly more than 70% of the student cohort for the first academic year were Aboriginal. This discussion highlights the implementation and formative evaluation of this partnership, and proposes recommendations for the effective planning and implementation of distance education initiatives.

Introduction

The need for greater understanding of administrative issues in distance education has been echoed by a number of authors. Murgatroyd and Woudstra [1989] observe that " Of all the areas of study in the field of distance education, the field of management appears most neglected" [p. 15]. Moore [1994] reinforces the need for examination of administrative issues. He suggests that " "the barriers impeding the development of distance education are not technological, nor even pedagogical . . . . The major problems are associated with organizational change, change in faculty roles, and change in administrative structures" [p.4].

These calls for more understanding of the administration of distance education have not, it seems to me, produced systematic attempts to link the basic questions in distance education to possible solutions which could be offered from fields such as business management and educational administration. This may be partly because the establishment of such a link will require adjustments in thinking in both fields. The discussions which do exist tend to deal with larger issues such as strategic planning or policy change. There is thus an emphasis on the "big picture" questions of institutional governance without an accompanying focus on how one successfully accomplishes the implementation of what policy makers decide "ought" to be done. Fullan's [1991] comments on this conspicuous gap are instructive here. He states, "Commitment to *what should be changed* often varies inversely with knowledge about *how to work through a process of change*"[author's italics] [p. 95]. In the case of program implementation, this statement appropriately expresses the distinction between the identified need for change, and actual program improvement.

In early September, 1995, three institutions in Alberta, Canada--the University of Alberta, Fairview college, and Kayas Cultural College--embarked upon the University Studies Project, a new partnership offering a selected number of introductory Bachelor of Arts courses in remote northwestern regions of the province . The primary mode of delivery was synchronized, multi-point videoconferencing (to as many as six sites) with all courses being delivered from the University of Alberta campus. Instructional support included the use of the Internet and a University of Alberta WWW page in conjunction with the videoconferencing medium. Slightly more than 70% of the student cohort for the first academic year were Aboriginal. This discussion will describe the implementation and report findings from a detailed evaluation of this partnership. The focus is primarily administrative in that recommendations will be provided for the effective planning and implementation of distance education initiatives.

The Project

Collaboration occurred between three quite distinct institutional entities: a comprehensive undergraduate and graduate level research university, a trades oriented rural community college, and a non-accredited community based organization, the primary function of which is to informally provide educational and other services to a geographically dispersed Aboriginal population. The theoretical framework for implementation encompassed problems and solutions at a number of levels including institutional cultures, planning and administration, instructional adaptations and course content, technological factors, student support systems, promotion, program costs, and legal/intellectual property issues.

Four 1st-year Faculty of Arts courses were selected for videoconferenced delivery from the University of Alberta campus. Implementation of the program began in late June 1995, and was essentially complete by the start of the 1995-1996 academic year, with most major operational elements in place. In September, 1995, the student cohort consisted of 39 students at three sites within the Fairview College system and at three sites within the Kayas College region.

The Evaluation

A research design with emphasis on multiple forms of data collection was deemed most appropriate for the evaluation. An advisory committee was set early in the process to define the parameters of the study and the evaluation questions, and to review the survey instrument and data collection procedures. Rather than a single researcher, a research team was used, both for data collection and particularly for data analysis and interpretation of findings. The research team consisted of the principal researcher (myself) and three research assistants.

Four methods of data collection were employed: (a) written surveys to students, (b) both individual and focus group interviews with counsellors, tutors, administrators, and instructors as were deemed necessary, © classroom observation of teaching and learning processes, and (d) document analysis. Interpretation of data and definition of findings was based on consensus among researchers, and therefore subject to what was, in essence, a continual peer review process. Additional verification of findings was obtained through feedback from members of the advisory committee, and where possible (in the case of interviews and observations), members of respondent groups, including students, counsellors, and instructors. This, and the use of a research team, enhanced the overall credibility of findings and reduced the possibility of bias by a single researcher in interpreting results. Findings from multiple data sources were used as a triangulation method to strengthen the validity of interpretation, results, and recommendations.

Findings are generally consistent with other recent research on similar programs [see Sorensen 1995]. In all, from a cohort of 34 students in December 1995, 29 usable questionnaires were returned. Out of all respondents, 26 students (90%) were 25 years of age or older at the time of the study, and 27 students (93%) were female. Nineteen respondents (65%) had one or more children under the age of 6 years, and 20 (69%) had one or more dependent children 6 years of age or older. A total of 14 students (48%) indicated some level of college training or completion of a college or technical school diploma as the highest level of education attained prior to admittance to the project. Another 10 respondents (approximately 34%) indicated completion of a general education diploma or high school diploma without matriculation. Although attempts had been made at a promotional campaign during the brief time prior to the start of classes, 15 students (slightly over 50% of the respondent group) had first become aware of the program through word-of-mouth. The main reason for students taking courses in the project was that they planned to seek university transfer and on-campus degree completion later. Of those responding, 22 students (76%) indicated this.

Based on student surveys, and through analysis of other data sets, planning and administrative issues stood out as one major area of concern. Students expressed a desire for more course and program information during the admissions and registration process, more effective program advising and counselling support, and improvement in turnaround time for screening and acceptance into courses. Thirteen students (52% of those responding) indicated a preference in the scheduling of courses for one-hour classes 3 times per week, and another 8 (32%) for one-and-a-half hour classes twice a week. The three hour block seemed to be the least preferred choice. When questioned on start-times for classes, 17 students (65%) indicated the 8:00 am to 4:00 pm weekdays time-slot as a preferred choice.

Data were also obtained on satisfaction with various aspects of the delivery medium and how these related to interaction, and on physical environment conditions associated with the medium and facilities provided. On average, students seemed satisfied with such factors as ability to concentrate, interaction with other students, class attendance, and disruptions. However, review of written comments by students showed concern over the extent of student-instructor communication, and also over student access to instructors through additional teleconferencing "office hours." Overall, students complained of the need for more convenient scheduling of office hours, and more immediate access to instructors.

A number of question items were designed to elicit data on the extent of contact, the ease of contact, and the value of consultation with counsellors, tutorial staff, and instructors outside of class time. It was found that significant percentages of students had much less contact with counsellors, instructors, and particularly tutors, than was originally assumed. The majority of those students responding appeared neutral on the helpfulness of consultation with counsellors, while 7 students (32% of those responding) perceived consultation with tutors as not at all helpful.

Overall, the most frequently mentioned weakness of the project was poor turnaround times for transfer of documents, assignments, and instructor feedback and assessments. Counsellors, instructors, and particularly students also reported a need for more university library support. Students called for access to more books and other materials,

BEST COPY AVAILABLE

and the possibility of small reference collections made available at various sites.

Despite these inadequacies, this program is considered a moderate success, given the approximate 51% completion rate and an overall mean grade point average in four courses for those completing of 5.2 (on a 9-point scale). In all, inadequacies in the first run of this project point quite clearly to the need for enhancements in the various forms of student support. Responses on administrative issues point to a need for more intelligent and adaptive policies and procedures for distance education programs.

Recommendations

Management perspectives in distance education will themselves need to become more educationally accountable. In part, this means that such perspectives must address the need for concrete and positive results in terms of completion rates, student learning, and overall student success. A focus on the effectiveness of implementation will provide greater understanding of the type of change which may be required, and at the same time constitutes an attempt to re-align administrative discussions toward providing clearer guidelines for implementation planning and action.

In attempting to contribute to such discussions, I propose that great advantage can be obtained by viewing the implementation of distance education programs as the *management of innovation*. The recommendations which follow stem from this basic premise. In essence, it is suggested here that such a view best enlightens what is actually taking place, especially in those initiatives where the institutions and stakeholders involved are relative newcomers, both to technology and distance education.

The suggestion that the implementation of distance education be viewed as the management of innovation will not be a new idea for those familiar with distance education literature or technological innovation. It is accurate to suggest, however, that the clear articulation of those characteristics of innovation which are most relevant to the implementation of distance education programs has not been forthcoming.

The following recommendations are best taken as guidelines for thought rather than as recipes for success. I suggest that these recommendations are not only relevant to the specific type of program discussed here, but perhaps applicable across a wider variety of distance education initiatives. They are as follows.

1. ***Comprehensive planning***. Given the obscure nature of innovation, any model, system, or plan for implementation will necessarily be comprehensive, in that it must account for multiple factors and variables influencing success, and therefore complex, in that the interplay among influencing factors and variables and program success will be far from simplistic or superficial in nature. Research knowledge, information, and evaluation findings relevant to the type of program being implemented will be a key element in the process of planning.

2. ***Collective change***. In order for the innovation to take hold and result in sustained educational improvement change must occur on an operational level; behavior patterns and the functioning of the organization must change in cooperation with change in the behavior patterns of individuals.

3. An interventionist approach. An interventionist strategy for implementation means that: (a) change is not initiated from within, by the group to be changed, but rather from without, by an external agent; and that therefore (b) a single and clearly defined innovation with a specific objective is planned and in turn linked to the strategic view of the change agent. In the case of the present initiative, change came primarily from the university side, however, it should be noted that the inter-institutional nature of the University Studies Project presents a special range of obstacles. In order to achieve success, change must occur in the habits of both institutions, partly based on how institutional responsibilities are defined. [See Jones & Lewis 1991, for a more detailed explanation of concepts related to recommendations 2 and 3 above.]

4. Flexibility, feedback, and organizational learning. Nothing is defined for certain. Innovation, by definition, will tend to be ambiguously defined and allowances must be made for feedback, assessment, and redefinition of any aspect of planning. The result of the innovation will be organizational learning, and in turn, this will require strategies and models with flexibility and feedback loops.

5. Collaboration. The nature of many important aspects of the initiative must be essentially collaborative in nature. There are two main reasons for this. First, collaboration goes hand-in-hand with enlisting the support from key stakeholders and decision makers which is so necessary to success. Second, collaboration allows members to assimilate and understand--to learn--what the initiative is really about. This, in turn, is an important step in changing the behavior of the organization itself, which in turn is the end goal of the change initiative.

*6. **Evaluation***. This component needs to be taken seriously as an important step in providing a knowledge base for policy decisions and program development. In part, this means that research questions and evaluation designs must be tailored to the nature of the project evaluated, and findings must be examined in the light of realistic expectations. Evaluation needs to be removed from the "back end" of program planning and be seen as an essential part of implementation itself.

*7. **Student support systems***. Extensive research findings indicate that no direct link has been established between delivery mediums, levels of interaction, and their effect on student achievement [see numerous studies including Fulford and Zhang 1993; Kendall & Oaks 1992; Ritchie & Newby 1989; Russell 1992, 1993, 1994; Stubbs & Burnham 1990; and Tobin 1995]. If these variables do not influence achievement, then what does? One possible answer seems to point in the direction of various forms of student support services. This was confirmed in the evaluation of the University Studies Project and has been suggested by others. Tobin [1995], after review of literature on the subject, explains, "Research with students, . . . indicates that their success is closely tied to the provision of these services" [p. 207]. Brindley and Jean-Louis [1990] reinforce a similar view with this comment : "We believe very strongly now that we must move in the direction of an interventionist model of support services" [p. 69].

Planning and implementing systems of distance education focused on the efficiency of technological functioning accounts for only one dimension of a multi-dimensional process. To take a more service-oriented approach is simply to recognize that along with technical operations comes a variety of administrative, instructional, tutorial, and other forms of support which appear to be critical to student success, and therefore intimately linked with educational accountability. A comment by Bates [1995] encapsulates the educational common sense of such an approach: "Technology is not the issue. The issue is: how and what do [we] want students to learn? . . . concentrate on designing the learning experience and not on testing the technology" [p. 14]. It is suggested that the recommendations presented above move toward this larger view of distance education programs.

Abstract
Education for students with special needs demands a large amount of funds, time and resource materials. This paper will address this problem by integrating special education strategies into a multimedia system within a regular education environment. Typical teaching methods and cognitive strategies for special education will be described. Issues arising from their implementation in actual education will be discussed. Based on the identifiable benefits of multimedia applications, the utility of multimedia concepts to address these issues will be discussed. A multimedia-aided teaching model for special education will be suggested.

1. Introduction

In the past, students classified as needing special education were educated in segregated special schools where a range of teaching methods and strategies were successfully developed and implemented. These specific teaching methods usually require customised instructional materials, additional equipment, specialised training, and a high teacher-to-student ratio. Currently, special education can take place in the whole spectrum of educational settings. In a regular school, it can occur within a special class, an educational support centre or a regular class. Special needs may exist across the academic, physical, behavioural or communicative dimensions [4]. Instruction within special education is individually planned, systematically implemented and carefully evaluated to assist exceptional learners to achieve successful outcomes and optimal independence. The current trend is to integrate most students with special needs into regular education. However, funds, time, resource materials, specially-trained teachers and support staff are scarce in this educational sector.

Multimedia in education has demonstrated benefits for improving educational quality. Assistive educational products using multimedia have extended the range of instruction available to suit the needs of students in special education. These use the multisensory capabilities of multimedia to offer presentations according to special needs. Multimedia can support more than one teaching method as well as enhance learning by more than one way of presentation. In addition, it can provide a flexible learning system which can address problems of funds, time and participation [15]. Flexible system delivery associated with educational computing technologies may improve the learning process in cost effective ways. This method can also increase access to educational opportunities for students and it can facilitate flexible participation for teachers and students.

This paper investigates the current teaching and learning strategies used in special education. The useability of multimedia in special education will be broadly examined. A model will be constructed based on the current infrastructure and philosophy in special education and the perceived benefits of multimedia to meet the needs of the students. Special considerations are suggested for the presentation of multimedia documents in the model. Issues which may arise from the applications of the model will be discussed.

2. Teaching Students with Special Needs

Special and regular education share a common goal which is to produce a student who can transfer learned skills to other settings. This enables the student to become an independent member of the wider community. Special education has its own set of pedagogical principles and practices. Some of their teaching methods have also been valuable for regular students. The most obvious differences, when teaching students with disabilities, are in timing and pacing needs. These needs are a consequence of psycho-motor, cognitive or sensory deficits.

Teaching methods in special education have derived from six main theoretical models: medical, developmental, ecological, humanistic, cognitive and behaviourist. This section focuses on the most popular methods emanating from the cognitive and behaviourist theoretical models.

The cognitive model has had a strong influence on special education methods, particularly cognitive and metacognitive training methods [6]. The cognitive theories explain such processes as attention, perception, memory, conceptualisation, comprehension, reasoning, problem-solving and decision-making. Different cognitive theories provide different explanations of the underlying cognitive processes. The information processing theory (IPT) is the most popular cognitive theory applied in the area of computing and is used as a frame in artificial intelligence design [8]. It provides an understanding of how sensory input is received, perceived, transformed, stored and retrieved. It is generally assumed that people with disabilities and learning problems have deficits in these cognitive processes.

The behaviourist model has greatly influenced the stimulus control and contingency management methods, precision teaching, mastery learning, direct instruction and computer-assisted instruction methods. Stimulus events such as screen prompts and accurate feedback are used to control the behaviour of students [6].

2.1 Cognitive and metacognitive training method

Generally, students with special needs have been described as passive learners [18]. Passive learners tend to attribute their successes or failures to forces over which they have little control (ability/luck), rather those they can control (effort/strategies). Passive learning can be caused by poor metacognitive knowledge, metacognitive control or motivational problems. Self-monitoring has been successful in promoting active learning [11]. Self-recording of the target event usually follows self-monitoring. The cognitive and metacognitive training method encompasses a similar approach to that of the stimulus control methods. Initial support is given, but with the aim of gradually transferring control for learning over to the student. Initially, the teacher describes the desired strategic behaviours by thinking aloud. Students imitate this by speaking aloud to guide their own thinking processes. Overt speech is gradually faded to covert speech so that the strategy may be internalised by the student. These methods have effectively taught behavioural, academic and interpersonal skills. After training, students may need to be prompted to use the learned strategies.

2.2 The stimulus control method

This method has had a profound impact on special education, but is seldom used in general education [6]. It manipulates antecedent events to encourage desired changes in learning or behaviour. The constant time delay (CTD) procedure is relatively simple to modify and highly effective. It has been used successfully with a wide range of disability types [20].

The initial series of trials in a CTD procedure contain a zero time delay. A task direction is given and the answer follows immediately. Subsequent trials use a fixed time interval for the control prompt. The best stimulus for the prompt for each set of tasks should be carefully selected at the design stage. Prompts can be gestural, verbal, pictorial, model actions or partially/fully physical. The CTD procedure has been successfully applied in CAI. It has been argued that the CTD procedure be used as a programming principle in the design of CAI for classified students. This would be equally valid for multimedia computer-assisted instruction (MCAI). A variation of delay intervals and presentation screens at strategic points during skill acquisition could be the subject of future research [7].

2.3 The VAKT method

This remedial method is also known as the Fernald method. It stipulates precise procedures for presenting stimuli and defines required responses from students. Prompts are gradually faded until students can learn the subject content without supports. At the beginning of the lesson, the student reads text out loud to the teacher. If a word is incorrectly pronounced or is not recognised within a reasonable time period, then it is recorded as an error. A multisensory procedure using visual, auditory, kinaesthetic and tactile stimuli attempts to correct the error. The teacher writes the correct word in large print and traces over the word whilst reading the word out loud syllable by syllable. This these actions. Lastly, the written word prompt is removed. The student then has to write the word and read it. The procedure is repeated until there are no errors. This method is really a combination of stimulus control and is done almost simultaneously. The student imitates multisensory strategies [6].

3. The Learning Environment

Let us assume that the knowledge to be taught has been selected and the course materials have been drafted. We now know *what* we will teach. The problem is, *how* will we teach it? At this stage, it is critical that the course materials be formulated to meet the student's special needs. The criteria for selecting teaching methods and strategies should be student-centred, rather than dependent upon the teacher's own preferred teaching methods.

601

The primary concern should be to determine the capacity of the classified student. The current scope of the student's skills and abilities needs to be identified. Then there are aspects of different learning styles, such as preferred stimuli and required adaptive devices for handicaps. These should be contemplated within the identified scope of the students skills and abilities. Analysis of the skills, abilities and learning style aspects will impact upon the instructional design for each stage of learning in the learning environment.

3.1 Skills and abilities

Skills, deficits and preferences in the following areas will have a primary impact on the learning development of classified students. These factors need to be considered in the instructional design:

- **Psycho-motor skills** are a combination of visual perception and fine motor skills, eg. drawing a square.
- **Sensori-motor skills** are a sensory experience combined with a motor response, eg. moulding dough.
- **Visual perception** is the ability to discriminate and categorise visual stimuli into meaningful patterns.
- **Auditory perception** is the ability to discriminate and categorise auditory stimuli and detect their patterns.
- **Cognitive skills** are ways that students encode, organise, interpret, store and process incoming information.
- **Metacognitive skills** are the conscious knowledge and control of our own cognition [6].
- **Exceptional abilities** can occur in classified students such as superior visual-spatial perception [10].

3.2 Learning styles

Learning style can be defined as the way in which a student learns best [9]. Learning strategies may be learned and developed. By contrast, learning styles are static and are relatively in-built features of the individual [14]. Adaptive devices for handicaps are part of the classified student's learning style. There may be preferences for different temperature levels, lighting and noise in the learning environment. Different levels of motivation and interest will be present. Some learners are more analytical and can pick out embedded elements contained in information (field-independent). Others prefer to be given concrete examples (field-dependent) [14]. The type of preferred stimuli, such as visual, auditory, kinaesthetic and tactile, to support each stage of learning needs to be identified [16].

3.3 Stages of learning

Generally, a student's performance can be conceptualised as occurring in three main stages:

- **Acquisition:** At this stage the basic skills and facts are acquired. Acquisition can be reinforced by a variety of presentation modes, such as speech, text, visuals, movement.
- **Fluency:** Drill and practice are vital to attain accuracy within a time frame. CAI has a proven record in this area [6]. It is able to deliver self-paced lessons.
- **Generalisation:** Generalisation occurs when there are correct responses in settings other than the training setting. This has been an especially difficult stage for students with intellectual disability or severe handicaps [9]. Training should include a systematic change of teachers, setting, materials, cues and reinforcers. Target stimuli should be as close as possible to a naturally occurring stimulus. An audio prompt of the sound of a telephone ringing is a natural stimulus when teaching telephone techniques. Research indicates that MCAI promotes a higher level of generalisation than traditional paper cases [13].

4. Multimedia for Special Educators

Multimedia in education has been described as student-centred, project-oriented and as amenable to collaborative learning. Interactive multimedia can be defined as the simultaneous use of data in different media forms, such as voice, video, text, graphics, animations, virtual reality [3]. The interactivity afforded by multimedia can facilitate more than one teaching method or strategy to optimise learning. Advances in compression and decompression techniques mean vast amounts of multimedia can be stored on optical disks. Faster read access from CD-ROM drives means speedy retrieval of large multimedia data linked to multimedia software. Developments in virtual reality are rapidly moving towards realistic three-dimensional forms. Some overall benefits of multimedia software for classified students have been identified:

- They are highly motivated to engage in learning via a multimedia system.
- Properly designed software can assist them with cognitive and metacognitive strategies.

- Undetected intelligences and skills, eg. visual-spatial were identified when working with multimedia.
- There is an increase in self-esteem.
- Multisensory nature of MCAI facilitate learning.
- Motion and interactivity holds the student's attention.
- Software is consistent and eternally patient [10].

4.1 Retention and recall

Students with disabilities often have difficulty organising and retrieving information. They need to be shown techniques which will support retention and recall. One technique is to cluster similar material into small chunks. This assists in encoding information ready for storage in long-term memory. Another technique is to verbalise a word whilst viewing it [12, 17]. Many researchers support the view that the use and delivery of multisensory information contributes to more effective learning. A combination of media, such as simultaneous audio-visual stimuli assists recall and leads to better retention. It is often said that we remember two-thirds of what we both see and hear.

Sound offers many possibilities. It can be a second or alternative channel of communication. It can be a stimulus. Narration can be used instead of long sections of on-screen text. Special sound effects can augment visual and narrative information. The visually-impaired can be assisted by screen readers that read text from the screen. Interviews with experts in a field can stimulate interest in a subject. Speech can be used to explain technical information. Speech synthesis technology enables the computer to deliver verbal models. Prompts can be paired with printed words and graphics that appear on the screen [5]. Music is effective for setting the pace or prompting the user. Voice recognition systems that dictate instructions to the system can be trained.

Multimedia together with videotapes or videodisc can provide and support tutorials, drill and practice, sensori-motor skills and simulation all in the one program. A meta-analysis of 63 studies that used interactive video instruction reported a positive overall effect size for interactive video (IV). This was slightly higher than previous effect sizes reported for CAI. This result reinforces the belief that the ability of multimedia or IV to depict real-life situations has an added effect for learning outcomes. Further, students who have difficulty relating to a graphical representation of a situation may recognise the pertinent elements if presented in a realistic video format [19]. Videos of case studies or interviews with experts are an inexpensive and effective way of assisting students to transfer their skills and knowledge to a real-world setting [2].

4.2. Conceptual model of multimedia system for classified students

It is necessary to have a conceptual model of how to multimedia elements can assist in the stages of learning [1]. Inevitably, the overall design of any multimedia system will reflect a philosophical viewpoint concerning cognitive development. But, there is nothing against combining elements from the various cognitive theories into the system [8].

In the past, multimedia authoring was restricted to developers with computing or artistic expertise. Current authoring software hides some of these complexities from the developer, and there is an abundance of ready-made multimedia resources. Still, it is not simply a matter of slotting in visuals and sounds to embellish the content. In fact, research has shown that overstimulating can inhibit normal functioning [6]. It is the quality and sequence of relevant inputs that is important, not the quantity.

The multimedia designer needs to begin with an established framework from which to view the overall project. Experience with the capabilities of authoring programs is essential. Strategies specified by the special education consultant need to be integrated into the design. Additionally, the multimedia designer will need to consider the ergonomic factors and user input interface for students with a diverse types and ranges of disabilities. So, knowledge of various kinds of user interface adaptive techniques and devices is essential. When the designer produces a multimedia document, the following guidelines should be considered:

- **Natural terms**

The multimedia document should use terms and metaphors which are familiar to the students. Some system-oriented terms may discourage the use of this system by the students.

- **Clarity and consistency**

The overall multimedia document should be clear and consistent so that the students do not get confused.

- **Easy to navigate**

Students should know where they are in the program and, if needed, how to leave the unwanted state without any embarrassment.

- **Recognition rather than memorisation**

The student should not have to remember information from one part of the document to another. Objects, actions and options should be easily recognisable.

- **Flexibility**

There should be an appropriate level of flexibility, so that target learners can search for information according to their learning style and cognitive ability [1].

- **Easy help system**

The students sometimes need to get help from the system. For example, the balloon help system on Macintosh seems to be acceptable, if it includes other media types such as sound.

The following model shows a multimedia system for special education within a regular teaching setting, Figure 1. The classified students are assessed prior to receiving instruction through the multimedia system. This valuable information is provided by the special education consultant and has considerable influence on the design of the system. However, further screening via the start-up screen in the multimedia program, may also be appropriate. For instance, metacognitive abilities, sound or visual sensitivity could be assessed and depending on the results, appropriate action could be taken.

Figure 1. Conceptual model for multimedia system.

4.2.1 Preparation of course materials in the subject domain

Initially, general knowledge about the subject domain will be extracted from the general library collection and databases. This knowledge is analysed and synthesised into draft course materials.

During formulation of these materials, the special education consultant will participate by selecting the appropriate teaching strategy according to his/her expert knowledge of the classified student's Individual education profile (IEP). The materials are then restructured to incorporate the chosen strategy. The document is annotated with detailed specifications of the steps in the teaching strategy. For example, to incorporate the constant time delay procedure, details of time delays and type of prompts should be inserted at points in the text. These course materials are forwarded to the multimedia designer for design and implementation into the multimedia system module.

4.2.2 Multimedia system module

This module transforms the educational information into various forms of multimedia such as graphics, animation, video clips and sound. It supports interactivity so that the students can easily interact and navigate the visible, audible and/or sensible information. Tasks of this module are handled by the multimedia designer with guidance from the educator. The designer is required to grasp effective multimedia techniques and artistic skills to manipulate the various media types. The multimedia document can be transmitted in synchronous or asynchronous mode depending on the needs and hardware available.

4.2.3 End users / students

The classified student interacts with the multimedia program by responding to prompts, highlighting text, choosing images, typing notes to the screen and answering questions. Adaptive input devices, as prescribed by the special education consultant, interface with the multimedia system for input and output. The student may need to access a database to search for various multimedia materials. Drill and practice and self-monitoring will be provided, where appropriate. The student can also create an audio or video clip and send it to the regular educator for analysis and corrective feedback. These interactions will contribute to the development of the student.

The capacity of the classified student will impact upon how well they process the information. Their capacity to learn is effected by their skills in psychomotor, sensorimotor, visual and auditory functioning, cognitive and metacognitive skills and exceptional abilities. Some learning style aspects such as motivation and interest level and preferred type of stimuli will also have an influence.

The classified student can communicate with their peers and the regular educator by posting queries on the whiteboard in the multimedia system. They can also send files containing results, graphs and case studies for marking and corrective feedback from the regular educator. The communications will also shape the development of the student.

In turn, the progressive learning development of the student, will have an effect on the development of their skills and abilities. Cognitive and metacognitive skills could improve as a result of strategic instruction in the multimedia program. As stated previously, learning styles are static and relatively in-built features of the individual. However, there could be indirect effects. If metacognitive skills are developed through instruction, then this could lead to a higher motivational level in their learning style.

4.2.4 Evaluation module

During the interaction with the students, affective outcomes such as satisfaction with the program can also be evaluated by the regular educator. After evaluation, the regular educator will compare the progress against the student's IEP and expected learning, analyse same and prepare a progress report for the Special Education Consultant (SEC). The regular educator and the SEC will confer to reach a consensus as to next step in the instruction program for the classified student.

The SEC then makes a decision as to the next step in the classified student's education. If the student has not made expected progress, then the SEC will select another teaching strategy and the instruction can then recommence according to the SEC's recommendations.

5. Conclusion

Different teaching strategies were investigated and analysed to pinpoint their suitability for transfer into a computerised system. Stimulus control methods require precise timing and repetitive actions and suit the strong capabilities of the computer to provide precision and reiterative looping. Auditory and visual prompts can be inserted at strategic points to support these methods. Similarly, the audio and visual capabilities of multimedia systems can facilitate multisensory learning procedures as described in the VAKT method. Cognitive and metacognitive training methods are structured and can be implemented through multimedia.

Some learning skills and abilities were described. Motor skills and visual / auditory perceptive skills can be enhanced through multimedia. Deficits in these skills can be assisted by using alternative approaches for multimedia presentation. Evidence was gathered about other benefits of multimedia for classified students. This information reinforced the belief that multimedia can have affective outcomes such as increased motivation and self-esteem. It also has potential to assist in retention and recall.

On this foundation, a new conceptual model was constructed for special education in a regular educational setting using a multimedia system module for delivery of the learning material. Interaction between the regular teacher and classified student is supported through the multimedia system, whilst retaining the expertise and support from the special education consultant.

Flexible learning can be more cost-effective than conventional modes of education, if the support infrastructure, such as courseware, equipment, and databases, is already in place. The initial set-up expense for this infrastructure is largely a one-off expense. The teaching strategies are contained within the multimedia program. This reduces the need for additional on-site specially-trained staff. Therefore, there is a reduction in recurring expenses. There is also a degree of self-instruction, self-assessment, self-monitoring and self-pacing in the multimedia system module. Interaction with the teacher is flexible. There is less requirement for a teacher to be continuously present for instruction. This decreases the demands on teacher time.

On the other hand, many staff members may not feel empowered by computer technology. As with any computer delivery system, reliable technical support is crucial to overall satisfaction with the system. Special education has been characterised by the higher level of support needed. Regular educators will need some training in special education, so that their interaction with the classified students is not impeded. The selection criteria for regular educators involved in this model will need to include specific personal characteristics which are needed in the special education area. Some examples are patience, persistence, high dedication and perception of special needs. At times, regular educators will need to communicate and consult with the support team consisting of special educator, physiotherapist, occupational therapist and other specialists in this field.

The purpose of the suggested model has been to address the pressures upon the regular education sector to meet the learning needs of classified students within reasonable budget parameters. The model could be extended to include other forms of flexible delivery modes such as the World Wide Web.

Abstract: This study has examined the effect on the level of anxiety of first year teacher education students after extensive course use of the WWW and E-mail. Two instruments were used. The first (the CAIN) measured student computer anxiety; it indicated that the WWW and E-mail experiences during the course had no significant affect on the level of computer anxiety for both genders. Student responses to a new instrument developed by the authors to measure computer-mediated communications (CMC) anxiety, administered at the completion of the course, were analyzed to determine whether CMC anxiety can be conceptualized as a unidimensional trait. The results indicated that 29 of the 34 questions in this instrument fell within the constraints of the Rasch model used. Hence, it is suggested that CMC anxiety can be considered as a unidimensional construct. Further research will generalize the CMC instrument as an evaluation tool.

Introduction

There are high expectations of teaching and learning with the World Wide Web (WWW) and e-mail, especially in higher education. In this era of financial cuts to higher education funding, it is hoped that the WWW and e-mail will: (i) provide cost-efficient and effective teaching mediums; (ii) reshape the conditions of teaching and learning; (iii) distribute access more equitably to potential students who are excluded on grounds of ethnicity/race, gender, disability, geography, and full-time work; and (iv) equip graduates for life-long learning in an increasingly technological world. Not surprisingly, there has been a proliferation of papers at conferences and in journals addressing various aspects of the utilization of the WWW and e-mail. Major recurring themes focus on programming tools, copyright, censorship, cognitive aspects of teaching and learning, and descriptions of the design and implementation of WWW subjects. There appear to be few studies measuring affective aspects of student learning using the WWW and e-mail.

[Levine 1994] argues that evaluation of computer-based programs should pay careful attention to factors such as the context into which they are introduced and students' perceptions of the learning environment. Such evaluations should include both cognitive and attitudinal data since success or failure of educational innovations is partly attributable to students' attitudes [Askar, Yavus & Koskal 1992]. [Goldfayl 1995] reinforces these claims, arguing that affective domain factors have largely been neglected by designers of multimedia materials and that they have undervalued the impact of affect on learning.

This paper reports on (i) the effect on computer anxiety of participation in a course that was predominantly delivered using the WWW and e-mail and (ii) the development of an evaluation instrument using Likert items to measure student anxiety towards the use of the WWW and e-mail, referred to in this paper as computer-mediated communications (CMC) anxiety.

Context

The Bachelor of Education program at James Cook University has a core first year subject, *Information Technologies in Education*, which, in 1996, was studied by approximately 170 students. Prior to 1996, the subject was taught in a traditional format of lectures and tutorial/workshops, the latter involved learning basic word processing, database, and spreadsheet skills. In 1996, the lecture material was delivered over a WWW-based Intranet. Three major reasons for this were: (i) cost effectiveness; (ii) relevance to a course on information technologies; and (iii) equity of access, particularly for those students who had full-time jobs.

Earlier unpublished research revealed a moderately high level of computer anxiety among members of a previous cohort of students in this subject whose exposure to computers was less than that of the current participants who had access to both computers and the WWW. Hence it was predicted that a lower level of computer anxiety would be manifest in the 1996 cohort of students as a result of their greater exposure to, and involvement with, computers, the WWW and e-mail.

Instruments

Computer Opinion Survey

The computer-anxiety measure used in this study was the Computer Opinion Survey [Simonson, Maurer, Montag-Torardi & Whitaker 1987] from which a score called the computer-anxiety index (CAIN) was calculated. The survey consists of 26 positively- or negatively-worded Likert-type items developed from a larger number of items that were considered indicative of a person's feelings of anxiety towards computers. The CAIN was found by [Simonson et al. 1987] to have an internal consistency reliability estimate of 0.94 and a test-retest reliability estimate of 0.90. Concurrent validity was tested by the authors of the test against the State portion of the State-Trait Anxiety Index (STAI). The CAIN was found to correlate significantly with the STAI score (r=0.32) as well as with a score based on the average of two observer's judgement of student anxiety when students were working with computers (r=0.36). The possible range of scores for the CAIN is 26 (26 answers of low anxiety value of 1) to 156 (26 answers of high anxiety value of 6), with higher overall scores indicating higher anxiety.

WWW/ E-mail Survey

The exploratory survey used as a measure of computer-mediated communications (CMC) anxiety consisted of 34 positively- and negatively-worded questions (Appendix 1) which formed, in this instance, part of a 72-item evaluation questionnaire administered to the sample at the conclusion of the semester-long course.

The questions in the 34-item set were considered indicative of a person's feelings of anxiety towards the use of World Wide Web and e-mail. The questions were dispersed throughout the evaluation questionnaire with a view to obtaining responses which could be analysed to see if a unidimensional construct, CMC anxiety, might be measurable.

Methodology

Students were administered the Computer Opinion Survey at the first session of the course as a pretest and also at the final session as a posttest. CAIN scores were obtained for the students' pre and posttests by reversing the responses for the negatively-worded questions and then adding the responses for each item.

In order to test the unidimensionality of the 34-item set of CMC anxiety questions in the course evaluation questionnaire, Rasch analysis was used [Rasch 1960/80]. Rasch analysis is a mathematical formulation which has recently been extended [Wright & Masters 1982] to handle Likert-type data. It is based on an Item Response Theory model and presumes that, in this case, it is the difference between the CMC anxiety of any person and the anxiety level of any item (its "difficulty" level) which determines the likelihood that any person will endorse any item.

The Rasch analysis enabled the students' response patterns to each of the selected set of anxiety questions in the evaluation form to be compared with their responses for all other questions in the set. Questions not demonstrating item-response patterns within 30% the expected values determined by the Quest computer program [Adams & Khoo 1993] were rejected.

The extent to which the anxiety questions conform to the estimations based on the Rasch model may be interpreted as evidence that all accepted items conform to the unidimensionality premise, that is, that all items measure the same latent trait, hopefully CMC, anxiety about the use of the WWW and e-mail. As part of the calculations to determine whether the unidimensionality premise had been satisfied, item difficulty levels and person "anxiety" levels were estimated by the Quest program. The requirement of unidimensionality of test questions is important in order that trait estimates (scores) can be meaningfully added to provide an overall estimate of CMC anxiety. It is argued that the use of Rasch analysis has direct applicability to this type of exercise where the responses to each item are to be simply added. The use of a factor-analytical model is regarded as being more appropriate when the particular construct is conceptualised as multidimensional; in this case, the raw scores for each factor require "weighting" according to the factor loading before adding the factor scores.

Results and Discussion

Computer Anxiety Results

Means and standard deviations for the group of students who were present for both testing times are shown in Table 1.

	Pretest		Posttest	
	Mean	Std. Dev.	Mean	Std. Dev.
Female (n=52)	57.00	18.12	57.15	21.70
Male (n=16)	48.56	14.34	46.50	17.36

Table 1: Pretest and Posttest Means and Standard Deviations for the CAIN Scores

A repeated measures ANOVA to look at gender differences yielded a significant gender difference as shown in Table 2.

	DF	Sum of Squares	Mean Square	F-Value	P-Value
Gender	1	2229.76	2229.76	4.01	.049 *
Subject	66	36729.85	556.51		
Tests	1	4.60	4.60	.03	.872
Tests * Gender	1	30.05	30.05	.17	.681
Tests * Subject	66	11638.85	176.35		

* $p < 0.05$

Table 2: Repeated Measures ANOVA for CAIN Scores by Gender

Given that the possible range of CAIN scores is 26 to 156, it is clear that the anxiety level at the beginning of the semester for both genders was not high, although the mean for females was approximately 9 points higher than that for the males. On the posttest, this difference had increased to almost 11 points. However, this change was the result of a decrease in the mean score for the males rather than an increase in the mean for the females. It appears that the experience of the females in the course did not alter their level of anxiety and concern with use of the computer. On the other hand, the experience of the males appears to have lessened their anxieties and concerns to some degree.

The prediction that there would be a significant decrease in computer anxiety is not supported by the results in Table 2 ($p = 0.872$). While the literature generally indicates that computer anxiety generally reduces with increased previous experience with computers, other research has demonstrated that this is not always the case. Factors such as computer access concerns and type of software used have been shown to affect this result [King 1994-5]. Some of the written responses gathered with the 72-item questionnaire also indicated a lack of computer access which may have contributed to the maintenance of the initial level of computer anxiety.

CMC Anxiety Results

From the Rasch analysis of the data from the exploratory 34-item CMC anxiety survey instrument, it was concluded that at least five questions were not measuring the same variable as the remaining 29. That is, these five questions had unacceptably high indices of misfit to the model. The varying degrees of misfit of each of these five items compared to the requirements of the Rasch model are illustrated in Figure 1. Acceptable levels

```

Figure 1: Rasch analysis output from Quest showing unacceptable misfit for 5 questionnaire items.

The five rejected items are listed below:
1. I did not access WWW lecture material on the WWW.
9. I used the WWW a lot before I started this subject..
19. I can think of many useful ways to use the WWW.
21. Links to other information from Web lectures caused confusion for me.
33. I was never anxious about learning from the WWW.

A number of reasons for the rejection of the above items can be hypothesized. Item 1 may have been rejected because both high and low CMC-anxiety students may have preferred the convenience of learning from a print-out of the WWW material rather than reading the material online. In relation to item 9, it is quite likely that both potentially high and low CMC-anxiety students may not have been able to obtain previous access to the WWW and, therefore, this question may have elicited similar responses from these two groups of students. As this and other first year university courses did not require them to look at other ways of using the WWW, item 19 may also not have discriminated between high and low CMC-anxiety students. The design of the WWW materials may have been the cause of confusion in item 21 rather than anxiety being a factor in this confusion. Use of the word, *never*, may have been the confusing factor in item 33 as even the low anxious students may have had anxious moments in learning from the WWW material at some point.

A further Rasch analysis excluding the five rejected questions still needs to be undertaken to determine whether the remaining 29 questions retain their unidimensionality.

Conclusion

This exploratory study has confirmed that this cohort of students who had comparatively low computer anxiety scores when they commenced this course, were not affected adversely by using the WWW for engaging with the lecture materials. Qualitative data not yet analyzed from the WWW/e-mail survey should help to clarify why the computer anxiety level did not decrease as was hypothesized earlier in this paper. This analysis may also help to explain the significant gender effect.

The use of Rasch analysis, in an attempt to develop an evaluation instrument measuring CMC anxiety, has resulted in a unidimensional set of 29 items. These may tentatively be used as an evaluation instrument for assessing the effect of the use of the WWW and e-mail for student learning. Further work, including a confirmatory Rasch analysis and generalizing some questions, needs to be undertaken.

Benefits arising from this study may include an efficient means of measuring affective aspects of student use of the WWW and e-mail. This may, in turn, help create a better balance between affective and cognitive concerns in this area.

Multi-user Interactive Concept Maps for the Learning Web

Rob Kremer
Knowledge Science Institute, University of Calgary
Calgary, Alberta Canada T2N 1N4
kremer@cpsc.ucalgary.ca

Abstract: Concept mapping applications can be embedded in the standard Netscape Web browser that allow several types of interaction among instructor and students. The range of interaction includes instructors posting structured information for later perusal by the students; "live workspace" remote lectures; remote interactive lectures; remote instructor observation and immediate correction of students' work; and remote collaboration among students. The concept mapping applications described here form a valuable tool in the learning web approach to education, described at previous ED-MEDIA conferences.

Introduction

Concept maps are graphs consisting of nodes with connecting arcs, which represent relationships between nodes [Lambiotte et al. 1984]. The nodes are labeled with descriptive text, representing the "concept", and the arcs are often labeled with a relationship type. Nodes may be represented using distinct visual attributes, such as shape and color, to distinguish node types; arcs may be similarly distinguished.

[Fig. 1] shows a concept map about whales by a first grade student. The arcs on the map are labeled with the relationship they represent: "EAT", "HAVE" and "ARE". The student was originally taught to do concept maps on paper without labeled arcs. He enthusiastically adapted to the software version and became quite at ease with labeled arcs after only minimal instruction.

Individual authors (both students and instructors) can compose concept maps to conveniently convey non-linear information structures, but *groups* of authors may also benefit from this flexible form of knowledge representation. Of course, software designed for groups, rather than for individuals, requires special attention [Grudin 1991] [Cockburn & Thimbleby 1995]. Besides the obvious need for the information to be placed in a repository conveniently accessible to all participants, various issues arise concerning participant awareness, security, data integrity, and role assignment. This paper will address one approach to the problem of designing software for use by groups: Concept maps are cast as interactive multimedia objects on the Web which can be embedded within HTML documents. Furthermore, the Web's usual distinct roles of authorship and readership are merged to produce a model of *participantship* which allows continuous incremental authoring of concept maps within Web documents — which have been traditionally regarded as fairly static. All of this may seem a bit abstract; so, several applications which exemplify this style of concept map use on the Web will be described.

Concept Maps on the Web

The Web is a useful and valuable tool to support the learning web [Gaines, Norrie & Shaw 1996] approach to education [Shaw & Gaines 1996]. Concept mapping tools can augment the standard Web tools to further support the learning web approach. This section and the next section describe several concept mapping tools which can be embedded in the standard Netscape Web browser.

The current version of the Netscape WWW browser allows concept mapping programs, written in C++, to be cleanly integrated with the browser such that users can interact with the concept map as easily as they might interact with a clickable image. Concept maps can be used just as though they were native objects to the

browser program. [Fig. 1] shows a Smart Ideas [Smart Technologies Inc. 1997] concept map embedded in an HTML document. This document and concept map are a student's report on whales. The concept map is actually a local hypertext of maps which can be navigated within its picture frame. The status bar just below the map contains the map's name within the local (within frame) hypertext, as well as a local "back" button for local hypertext navigation. The concept map itself can be re-arranged by simple direct manipulation commands. Nodes and arcs in the map carry visual attributes to indicate their type. Drop-down shadows on nodes indicate that the node may be clicked to navigate either to another local map (within the current document), or to a different Web document.

All this is possible through the *plugin* Application Program Interface (API) provided by Netscape. Plugins are programs which register themselves with the Netscape browser in association with a specific MIME type [Borenstein 1993], and are dynamically loaded by Netscape whenever an object of that MIME type is displayed. Plugins can be either embedded in an HTML document or displayed as complete documents themselves. Plugins may also interact with the Netscape browser and with the enclosing HTML document such that the plugin may affect changes to the HTML document (including other plugins). Likewise, interactive elements (such as buttons) in the HTML document may send messages to the plugin. [Fig. 2] shows a KSIMapper [Kremer & Flores-Mendez 1997] concept map embedded in an HTML document which contains many objects which interact with the concept map. A similar program, written as a Java applet, has also been constructed and described in these proceedings [Flores-Mendez 1997].

Groupware Aspects

While concept maps can be very useful as Web documents, their usefulness can be dramatically increased by making them multi-user interactive documents. That is, the traditional distinctions between document author and reader (instructor and student) can be dissolved to create a *participant* role, where (sufficiently privileged) individuals can not only browse a concept map but also change the document and store the modified document back to the server. Furthermore, if two or more users happen to access a particular document at the same time, they should be able to smoothly move into a synchronous shared editing session. The simple interaction

Figure 2: A concept map embedded in a HTML document using HTML forms input elements and JavaScript to achieve a custom user interface.

architecture outlined here allows any number of users to interact. This "free and easy" mode of peer interaction is critical to support the learning web model of education.

Allowing users to update concept maps from a Web browser is accomplished through use of the CGI (Common Gateway Interface), available on most WWW servers. A shared concept map is not directly referenced by its normal URL; instead, a custom CGI program is referenced, and this reference is parameterized with a reference to the actual concept map document. When the URL is fetched by the client browser, it is the responsibility of the CGI program to return the concept map data on behalf of the server.

When the client wishes to save the concept map, the same indirect URL is used, but with the concept map data as part of the *post* message. The CGI program is called by the server, and the CGI program copies the data back into the original file on the server.

Of course, this simplistic approach is open to malicious or accidental disruption of the data. A host of security issues come to mind. While these issues have not been addressed so far in this research, there are many well-tested solutions elsewhere. Version control, which can be as simple as maintaining a new version of a file every time it is written back to the server, is one approach; public-key encrypted electronic signatures being verified on a write-back is another.

Merely allowing users to write concept maps back to the server is not enough. Besides the obvious dangers of users overwriting each others' work, users need to be kept aware of other users concurrently accessing the

BEST COPY AVAILABLE

concept map and what the other users are doing. Each user's concept map must also be synchronized so that all users are observing the same map.

Since shared concept map access is through a server CGI program, this program can take responsibility for recording access as part of the concept map's history, and for coordinating "real time" interaction between concurrent participants. Thus, clients can obtain information about past and current participants from the server (as in [Fig. 2]). Furthermore, since the software architecture uses *command objects* [Gamma et al. 1995] to encapsulate all user updates to a concept map's state, these command objects can be sent to the server where they can be re-broadcast to all concurrent participants. In this way, each of the participants will receive all participants' commands, and all participants' concept maps will eventually arrive at the same state. (There are many finer points to this kind of interaction, but they will not be discussed here.)

This form of interaction has the advantage of being serendipitous; that is, users need not go to any special trouble to set up a "conference"; instead, interactive sessions are automatically set up by virtue of concurrent access to the same concept map. This not only avoids the complex "conference setup" of many groupware tools, but also supports a natural *places*, or *rooms* metaphor — participants can serendipitously meet other participants at some location (Web page) or may specifically arrange to meet at a certain location (Web page) at a certain time. See [Roseman & Greenberg 1996] for a discussion of this kind of interaction.

Application

As already mentioned in the introduction, concept maps' flexibility allows for a variety of applications within the educational field. This section describes several applications where Web-based concept mapping tools, in particular, can be used.

"2½-d" Guide To Information Objects

If one ignores the groupware possibilities and follows a more traditional instructor/student model of Web authoring, concept maps can play a role on the Web very similar to that of clickable images. An instructor designs and constructs a concept map off-line, then posts the finished product on the Web; students do not have any ability to modify the artifact. [Fig. 1] is an example of this sort of "read-only" Web concept map. Although students cannot change the map permanently, they can perform certain actions, as prescribed by the instructor, such as clicking on a node to navigate to other information.

In the case of Smart Ideas concept maps, which encapsulate a local hypertext of concept maps, the instructor has a choice of a node either being a hyperlink to another Web document or being a local hyperlink within the local hypertext of concept maps. In the later case, the Web document remains displayed; only the sub-window in which the concept map is displayed gets replaced by the new map. A local "back" button helps to maintain the students' context by providing the ability to backtrack.

Typically, well-written Web document collections use lists of links as a "table or contents" to aid readers as they navigate through the material [Tilton 1995]. Concept maps can be used to the same end. Rather than a simple table of contents list, the reader can be presented with a concept map describing the document collection. The reader can then click on the concept map nodes to navigate the site. In this scenario, the nodes represent possible destinations in the information space, and arcs represent the relationships between them. Concept maps have an advantage over simple (or even hierarchical) lists in several areas:

- Concept maps can convey *structure*. That is, besides the sequence and hierarchy that lists can display, concept maps can visually display cycles, containment, and other complex structures.
- Concept map links can be typed (labeled or otherwise visually distinguished) to make *relationships* among the nodes explicit. Lists have no means of displaying relationships among elements other than simple sequence and generic hierarchy.
- Concept map nodes can be visually typed (by surround shape, color, and style) to convey quite a bit of information to the student experienced in reading a particular style of concept map. For example, a concept

Figure 3: A concept map developed by a three member group brainstorming network design [Kremer 1993].

map of a programming structure can use shape and color to distinguish various object types such as *library, function, class, abstract class, concrete class, exception class, file, source file,* and *macro.*

Concept maps suffer from their tendency to take up more precious screen real estate than lists, but often this can be mitigated by scrolling and nesting maps.

Presentation Planning

Traditional hierarchical outlining techniques force authors into a great deal of premature planning. Hierarchical outlines force an early decision on the order of presentation. Furthermore, complex non-hierarchical relationships that may be inherent in the material may be difficult to represent in the outline. Both of these problems are neatly solved by use of concept maps: Points can be listed as nodes without inherent order; and complex relationships between them are represented naturally and easily by arcs.

It should be noted that, even after the construction of a complete concept map of a particular topic, one must *still* "linearize" it if the topic is to be presented in more traditional medium, such as a paper or a talk. Concept mapping gives the author a convenient intermediate point to bridge between raw ideas and an organized, linear presentation.

Brainstorming

Concept maps are good tools for student brainstorming sessions. The scenario here is a group of learning web students working together on a project. The nodes and arcs act as concrete symbols for ideas, and the arcs allow one to draw complex relationships among them, arranging, comparing, contrasting, and grouping ideas. Concept maps can be used for brainstorming by groups of students for planning projects, "outlining" papers, or assembling presentations. [Fig. 3] is an example of a concept map developed during a group brainstorming session on the design of a computer network.

BEST COPY AVAILABLE

Observation and Interaction

The real-time interaction facility of Web-based concept maps allows instructors and students to interact, even when they are not in the same location. Assuming a second communications channel for audio, teachers may give instruction with full illustration though the shared concept map as a work surface. The concept map may be pre-existing or may be developed over the course of the instruction. In either case, the "live" surface allows for detailed extension, pointing, gesture, and animation. Furthermore, depending on the situation, students may be allowed to extend and modify the concept maps during the instruction.

Reversing the roles, students may develop a concept map as the instructor observes from a remote station. Errors made may be immediately corrected by the instructor, since the instructor can have full access to the work surface. This flexibility is ideal for the learning web approach to education.

Summary

Concept maps are an intuitive form of knowledge representation. While concept maps are useful for traditional presentation, their utility can be enhanced by making the concept mapping tools multi-user tools. As such, maps are stored in a central repository where instructors and students could read, edit, and update them: an ideal technology for use in the learning web approach to education.

In this approach, data integrity is simply and naturally maintained by allowing multiple users to interact in real-time whenever more than one user accesses a particular concept map. That is, each user's map is always up-to-date because every user's state-changing activities are broadcast to all the other concurrent users of the same map.

"Media +" - A Multimedia Environment for Constructionist Learning.

Dr. Nira Krumholtz, Adi Markuze-Haas

IDEA Center - Department of Education in Technology & Science
Technion - Israel Institute of Technology
Israel
E-mail: ttrnira@techunix.technion.ac.il
adim@mofet.macam98.ac.il

Abstract: A learning environment based on constructionist approach is presented. "Media+" supports learning that is directed towards construction of an external product. Construction is carried out using a multimedia authoring tool. Learners engage in independent study of a subject, they form their own leading theme for researching and learning their subject, they plan, design and construct a multimedia presentation which reflects their grasp of their subject. A special emphasis is placed on encouraging and instructing teachers in adopting the new role required by the environment. Students and teachers participate as equals in evaluating the students' achievements in all facets of learning. Preliminary evaluation shows that significant learning takes place in "Media +" classes, including features which may be attributed to constructionist learning. "Media +" is implemented in 60 classes in middle schools in Israel. In 1997 80 teachers will join the project after having received a full year preparation course.

"Media +" is the name of a multimedia environment designed for supporting a constructionist approach to learning. "Media +" was developed and is being implemented in schools all over Israel by IDEA[1] center. In this paper we describe the environment, explain how it supports constructionist learning, and describe the role multimedia play in this process. Finally we show how the environment is implemented in a middle school science class, and present data to show the occurrence of meaningful learning in this class.

The constructionist conception of learning advocated by Papert [Papert, 1980] assumes a central role for the construction of an external product that can be shared with others. Papert emphasizes the product being external to the learner, in order to distinguish it from the constructivist concept of learning as an internal process. In radical constructivism, learning as the construction of mental schemes is an exclusively internal process [Glasersfeld, 1995]. As such, it is accessible to others only indirectly. When guiding the learner to construct some external expression of learning, an element of communication is involved, which permits a less indirect awareness of others to the fact that something has been learned. The distinction between constructionism and constructivism is crucial to anyone whose main concern is with the application of learning theories in the classroom. Within a constructionist approach, we can visualize a working model that incorporates both internal processes of constructing knowledge, and external influences of the surrounding context. We require a working model that permits multi-lateral communication involving both teacher and fellow learners, assigns a distinct role for the teacher, and lays down a basis for evaluating various facets of learning that occurs within its framework. A working model based on the constructionist conception enables us to foster an interplay between internal and external learning activities that is expected to promote mental creative activity [Shaw, 1996]. "Media +" was designed as an environment conducive to active and creative learning.

Conceptual Guidelines for the Environment

The environment was designed on the basis of some general assumptions concerning the process of learning. We assume (with many others) that meaningful learning occurs if:

1. the learner is free to construct her/his own perception of the information brought to her/his attention;
2. the environment stimulates curiosity, permits free choice and independent study, and supports self-motivation;
3. the environment supports learning through creative processes;
4. the environment is free from irrelevant or intimidating interactions which stifle the natural curiosity of the learner.

With these assumptions to guide us, the learning environment was designed. Its main features are:

1. Learners choose a central theme for their independent study within a given subject.
2. Learning is centered about the construction of a product, a computerized multimedia presentation.
3. Learners make their own decisions and choices when constructing the presentation, so that it reflects the insights and knowledge gained by them throughout this process.
4. Learners achieve mastery of the multimedia tools as they proceed with their design and construction of the presentation..
5. Learners participate as equals with teachers in evaluating their own performance.
6. Learners are encouraged to work in teams, to exchange interesting findings, to share ideas, and to discuss problems and possible solutions.
7. Teachers assume a role of guidance and assistance, and are taught to encourage their students to share responsibility for their learning.

A General Description of Learning in the Environment

Learners are aware of an objective - the construction of a multimedia presentation - from an early stage of their studies. Most learning activities are motivated by needs that arise out of the process of construction. The learner gathers material, conducts research, organises and processes information in a way which would best express her/his gradually developing ideas. Throughout the process, the learner implements cognitive skills of information processing, classification, rational selection, problem-solving and decision-making.

In addition, the learner is encouraged by the teacher to form her/his conception of the appropriate way to evaluate her/his own work, and to offer parameters that will be relevant for evaluation. Self evaluation may occur continuously, or at specific intervals determined by the learner during the period of learning.

The construction of a multimedia presentation adds tasks of expressing and presenting information and ideas in a non-verbal form. Our assumption, to be tested by further research, is that the use of multimedia fosters additional cognitive skills, not normally activated in a classical text-based learning environment. Thus we consider that "Media +" introduces a use of the computer as a pedagogic tool [Salomon, 1993]. Some preliminary findings point to the possibility that the active use of multimedia may contribute towards improved understanding of concepts [Bar-On, N. & Ben-Sasson, Z. 1997].

Learning to use the multimedia tool proceeds gradually. The teacher points out the possibility to use media, and guides students in their use, at various periods during class hours. Instruction in the use of multimedia is carried out in one of two modes:

a. The teacher identifies situations where varied expression, or creative activity may contribute to the acquisition of a new concept, to broadening insight, or to the general grasp of some phenomenon. Accordingly, the teacher exposes the students to the possibility of using graphics, colour, sound, motion etc. in relevant situations. b. The teacher announces that a specific tool will be introduced at a certain time, and anyone who wishes to learn how to use it, may join in. The first mode is employed mostly when the students are novices in the environment. Later on, they learn to identify their own needs in terms of use of the media, and ask to be instructed, or learn by themselves, the required functions.

It is important to state that the process is gradual for novices in the environment. Our 13-15 year old students gain mastery of the multimedia tool very quickly; by the time they start work on a full scale presentation, the program serves them as a real tool for self expression and creative activity.

Stages in the Progress of the Learner

Learning of a specific subject is divided into two stages. In the first stage, the teacher introduces the main subject to the students in a manner designed to stimulate curiosity and create a high degree of interest, either in the subject as a whole, or in some issues related to the main subject. We termed this stage "the exposition stage". The objective of this stage is to assist the learners in forming a general picture of the subject, to hint at the main themes it features, to expose possible points of interest for further research. At the end of this stage, each learner is expected to have formed her/his leading idea, either in the form of a question, a hypothesis, or a statement, which will serve as a central theme for her/his multimedia presentation.

The second stage is the independent study and construction stage. Each student is guided by her/his leading theme .Her/his learning activities are motivated by the need to construct a tangible product. There is no other incentive for learning. There are no exams. The use of multimedia plays a central role at this stage. As the student gathers the relevant information and develops her/his own conception of the leading theme, she/he also plans the structure of the multimedia presentation. Learners have complete freedom as to the design of their multimedia presentations. They are encouraged explicitly to make use of any medium, or any integration of media that would best express whatever they wish to express, be it interesting findings, personal point of view, the development of their own understanding of their theme, or anything they regard as relevant to their theme.

It is at this stage that the learners have opportunities for going through an interplay between internal and external learning processes. On one hand, they are involved in learning through independent research; on the other hand, they try to organize, adapt and design their knowledge and insights in order to integrate them in their product. The teacher may offer them points for consideration, but they also have a wide scope for creative activity. Their treatment of any and every issue connected to their work is always multi-faceted, bringing into account simultaneously questions of content, relevance, planning, design and presentation in multimedia.

While learners are engaged in their independent study, the teacher offers assistance and guidance in answer to their needs. At an early stage the teacher introduces the issue of evaluation. Students address themselves to questions such as what is the role of evaluation, how it may benefit them, and who should be evaluating whom. In "Media +", students participate as equals in determining the parameters for evaluation of their work. Parameters that may be considered include skills, knowledge, all the stages of planning and construction, and various aspects of the final product.

During a learning period each team can present its "work in progress". This may be done in several different ways. When advising who are about to present their work, the teacher stresses the fact that "work in progress" is to be understood literally, that is, it is unfinished and should not be expected to be complete in any sense. When presenting their half-way work, students may ask for any kind of feedback they wish to obtain from their peers. They may present whatever aspect they choose of their work, explain their leading theme and why they chose it, describe difficulties, ask for advice in some function of the program, tell why they chose specific visuals or vocals, and in general share with their peers whatever they wish to share. Teachers are advised to allocate 20 minutes for "work in progress" reports at the beginning of each class period.

Bumps on the Road

Some major difficulties should be pointed out. First, teachers have a hard time relinquishing their accustomed control over all activities in the class. They are expected to step off center stage and offer their assistance to the students in answer to their various needs. At the same time, they have to monitor the differential advancement of the teams, and intervene were and when they may be of most help. "Media +" head team helps teachers through courses, team support meetings and refreshment day-courses.

The second major difficulty is the intervention in the daily routine of school hours. "Media +" puts a heavy load on school hours and demands the co-operation of headmasters and many others from the school staff apart from teachers of the experimental classes. The load is heavy in more than one respect; "Media +" is certainly more time consuming than other learning methods. Teachers have to meet with teams - that is, pairs - of students several times during the leaning period. They have to learn efficient time-management among other things. "Media +" may be considered expensive because of the need to buy multimedia software, and pay for instruction for the teachers. However, the bulk of expenditure at the outset of the project in schools was met by the Israeli government, following a policy intended to upgrade learning and teaching levels in middle schools in Israel. In 1997, schools that join the project are usually equipped with the required hardware, and do not hesitate about purchasing the software. They may have a problem with financing staff instructors. Experience shows, however that if a school decides to join "Media +" on the basis of its educational credo, the management is not deterred by funding difficulties.

Implementation of "Media +" in a Science Class

"Media +" has been implemented for the last three years in some 30 classes in middle schools in Israel in experimental form. It is applied to the study of various subjects ranging from literature and history to science.

A preliminary evaluation of the environment was conducted in four 8th grade classes [Bar-On, N. Kampinsky, H. Ben-Sasson, Z. & Malka, H. 1996.]. We describe here the process and results from a science class.

The main subject was "heat and temperature". The focus of interest at the exposition stage was an experiment demonstrating phase changes of water through thawing and boiling. The experiment served as a source for questions raised by the students. Gradually, while discussing points of interest and clearing some unfamiliar terms, each learner discovers her or his personal interest in an issue related to the main subject. After the exposition stage, students chose themes according to personal interest and ability.

Some of the themes were: "How does a thermos flask function?", "What is the fate of the heat of a bonfire?", "How can a snow igloo retain warmth?", "Can the boiling point of water be changed?" "Why does a nuclear reactor produce heat?" The wide variety of themes reflects the variety of interests, and also, the differential ability of students to elaborate their own themes. Students were encouraged to look for materials in a wide variety of sources, and to include visuals, vocals and motion, as well as textual materials in their multimedia presentations. All learning of heat energy concepts was integrated in the research and planning of the presentations.

Research Results

Comparing several facets of learning between a "Media +" class (28 students) and a control class (26 students) at the same school, it was shown that:

1. In terms of general content knowledge, "Media +" students' achievements were roughly equal to or slightly better than those of the control class. In 7 items which tested content knowledge, the scores were [in % of correct answers, control group in parentheses] 76 (60), 17 (8), 70 (81), 50 (30), 70 (27), 25 (14) 81 (75).
2. "Media +" students showed an increased aptitude for asking questions. When confronted with an imaginary problem situation (you have to transfer heat energy from the sun via the moon to Earth, to prevent cooling down of earth), experimental class wrote 64 questions compared to 42 written by control class. Questions written by experimental class covered a greater variety of issues related to the original problem
3. "Media +" students were more ready to attempt an assignment of mapping concepts from a list. The list was composed by the tester, based on a list supplied by the teacher, of concepts that were learned. 26 "Media +" students undertook the assignment, compared to 13 of control; and they incorporated a larger number of concepts into their maps: 106 compared to 61 in the control class. In this assignment, students were permitted to add concepts that seemed important to them, and were not included in the list. 14 "Media +" students added new concepts (not included by the tester), compared to 5 control students who did the same.

Other items in the test show that "Media +" students have greater readiness to cope with unfamiliar or difficult subjects, and a more varied conception of what is a "central concept". In interviews, a great majority of the students expressed distinct preference for studying in "Media+". They said that this method of learning was much more interesting, mainly on two counts: the use of multimedia, and the fact that they worked on "their own thing". "Media +" was described by a majority of nearly 90% of the students as "great fun" "a great way to learn" etc.

A repeat of the test 3 months later shows that "media +" students retained more of the content learned compared to the control class. Results in the form of percent of correct answers to content questions show no decrease in number of correct answers of "Media +" students, compared to an average 30% decrease in correct answers of control students.

Results from 3 other schools confirm the general picture. "Media +" students may achieve slightly greater, or equal content knowledge compared to control groups. It is evident however, that they utilize a greater variety of skills, gain confidence in their abilities and learn to assume responsibility for their learning.

Conclusion

We conclude that "Media +" has achieved the following:

1. Students have improved their ability for independent study: they learned to ask questions, use various sources of knowledge, plan, design and process newly acquired knowledge to make it their own.
2. The multimedia presentation offers a wide scope for self expression and encourages use of the computer as a pedagogic tool. It promotes creative activity and construction as an integral facet of learning.
3. Learning through construction is a motivating experience and seems to be conducive to in-depth understanding, and longer-lasting memory of concepts learned.
4. The open, friendly and stimulating environment tends to make the experience of learning a pleasant one, and may enhance constructive processes of learning.

Center for Complex Systems Research, Beckman Institute
mlam@ccsr.uiuc.edu

Alfred W. Hubler
University of Illinois at Urbana-Champaign, Department of Physics
Center for Complex Systems Research, Beckman Institute
alfred@ccsr.uiuc.edu

Abstract: The CyberProf conferencing system, known as the NetworkTA, is a Web-based system for interacting and collaborating in an educational environment. The NetworkTA is integrated into a very sophisticated software package known as CyberProf, an intelligent human-computer interface for grading, creating, and presenting educational course materials on the World Wide Web. The design of NetworkTA, like that of CyberProf, exploits complex systems theory in particular methodologies for control chaos and attempts to enhance the student learning process through nonlinear resonance. We explore the use of these methodologies in the context of a conferencing system.

Introduction

The World Wide Web is an excellent medium for communication, with widespread accessibility and the ability to deliver text, sound, and images. CyberProf, an intelligent, interactive human-computer interface created at the Center for Complex Systems Research in association with the Beckman Institute located on the University of Illinois at Urbana-Champaign campus, was developed as a teaching tool which intelligently presents and grades educational course materials through the World Wide Web. Development of the NetworkTA is based on CyberProf which already successfully applied complex systems theory [Cowen et al., 1994] [Forest, 1991] [Lam and Naroditsky, 1992] [Hubler and Assad, 1995] [Bloom and Hubler, 1996] to development of homework and lecture notes in online instruction. Examples will be described to illustrate how the NetworkTA (the conferencing system component of Cyberprof) creates a collaborative environment which can exploit psychological resonance among students.

CyberProf and the NetworkTA can be obtained free of charge. Interested people are welcome to visit CyberProf on the World Wide Web at http://cyber.ccsr.uiuc.edu/cyberprof/, and can engage in a demonstration version of the NetworkTA at http://cyber.ccsr.uiuc.edu/dpt-bin/1997/0.6/cyberprof.cgi?CPscriptname=nta06. In addition, several courses at the University of Illinois use CyberProf and the NetworkTA and offer guest login to the NetworkTA.

The NetworkTA for Electronic Conferencing

Electronic conferencing is beginning to impact the way people learn and interact. Email and electronic conferencing allowed students to conduct group projects in educational psychology courses at the State University of New York College at Cortland. Participation in the electronic conferencing was silently monitored and evaluated by the instructor and questions were answered when necessary [Anderson, 1995]. Online conferencing was used to evaluate writing skills for elementary and high school students and was found to be an effective instructional tool that also transformed the classroom from a competitive environment to a cooperative one [Stuhlmann and Hochella, 1995]. Business students at Northeastern University reported improved quality of instruction and better access to instructors as a result of email and computer conferencing [Zack, 1995]. Computer conferencing was used to teach writing skills [Leppanen and Kalaja, 1995].

In addition, electronic conferencing through a widely available medium removes the space and time constraints allowing more flexibility for students and instructors while introducing students to using technology. The role and impact of computer communication in education are detailed in various literature [Manrique, 1994] [Berge, 1995] [Harrington and Hathaway, 1994].

The NetworkTA is a Web-based conferencing system which provides a medium for interaction and collaboration between students and the course director. The NetworkTA capitalizes on the Web's ability to allow interaction without the need for physical and temporal proximity. Everyone can participate in any convenient location such as a campus computer lab, a dorm room, or a home many miles away from campus. Widespread accessibility to the NetworkTA can promote communication and collaboration on homework, projects, and other assignments. Also, the NetworkTA is easy to use. The NetworkTA accomplished this by exploiting the Web browser paradigm. The layout of objects, such as icons and descriptive text, is arranged to be visually easy to interpret. Menus, hypertext links, buttons and text boxes allow user interaction with the software. The NetworkTA's accessibility and an easy-to-use interface facilitate and enhance student interactions.

What distinguishes the NetworkTA system from other conferencing packages is its effective use of complex systems. Consider a harmonic oscillator. The system resonates when the forcing function matches the rhythm of the oscillator. It is conjectured that this concept can apply to a complicated system such as communication. Communication through the NetworkTA can produce strong interactions for students with other students. Students consult with online student tutors and fellow students to whom they can relate effectively, resulting in psychological resonance. This can be explained in terms from complex systems theory. The online student tutor (or classmate) mirrors the dynamics, behavior, and ideas of the student very closely. Next, the online tutor (or classmate) intentionally deviates slightly from the mirroring in order to impart information which guides the student in the correct direction. How the NetworkTA strives to accomplish this is described in examples of its use in courses at the University of Illinois.

The NetworkTA Conferencing System

Economics

At the University of Illinois, the NetworkTA serves as a chat forum for Professor Jane Leuthold's economics courses. Through online conferencing, this course director creates an environment where students can freely participate. Because participation in the NetworkTA is recorded and graded, many students contribute to the discussion. In addition, no bonus or penalty points are assigned for "good" or "bad" writing samples so that students are free to address the discussion topic, express their opinions, and develop writing skills, under less pressure. In the process, students help each other develop their own thoughts. The course director's enthusiasm for electronic conferencing through the NetworkTA, an alternative to conventional face-to-face exchanges, encourages students to contribute the online discussion.

The structure and organization of the NetworkTA conferencing system foster this development. Messages are threaded and grouped by initial topic thread as shown in [Fig. 1]. Messages are further grouped into discussion boards. Finally, discussion boards can be even more highly organized into layers of discussion boards, folders of discussion boards, and folders of folders, and so forth, similar to [Fig. 2]. In the example shown in [Fig. 1], the course director begins the discussion board by composing a new message which introduces the chat topic on which she has chosen for the students to debate.

> Our first chat topic deals with the issue of internet pricing on campus. Check out the UIUC policy for internet pricing described at http://www.uiuc.edu/ccso/announce/tscharge.html. See if you think the campus is using an effective pricing scheme for allocating this scarce resource. Would you suggest any changes? Post your opinion to the Chat in the form of a short paragraph. Feel free to comment on the opinions expressed by other students -- the purpose of the Chat is to provide a forum for economic discussion. Maybe we can come up with some suggestions to improve the internet pricing system on campus!

Shaun, the student with login name *smcarlso*, follows the discussion board by reading the course director's introductory thread through a mouse click on the hypertext link. Next, he starts a new thread detailing his opinion.

> I think that what U of I has done with the pricing is very fair. To start, every student with an account has the right to 20 free hours dial up access. For most students, that is more than enough time to get done

> whatever needs to be done through the network each week. Also, if they need more time, they can get it at a rate of only $.30 an hour. That is more than reasonable…

Students read Shaun's message and interject their own opinions by responding directly to Shaun's posted message in the same thread (shown in [Fig. 2]) or by initiating a new thread (not shown). Students freely respond to each other in these discussion boards because they share similar experiences and express their thoughts through their writing using the familiar forms of colloquial and formal language. Through, the NetworkTA, strong interactions among students who relate to each other extremely well can result in psychological resonance.

In the above examples, simple text and a single hypertext are used in the message. However, messages in the NetworkTA can also include text, sound, still images, video, and special HTML extensions specific to CyberProf, including LATEX-like commands for typesetting of mathematical expressions and special symbols. To simplify exploration of messages, only the top level message of each thread is emphasized and all threaded daughter messages are associated with the top level message. Information such as subject heading, topic line, author, and thread number uniquely identify the original message of the thread. The subject heading for each message introduces the content of the message which may lure the student into reading the message. Because several participants can simultaneously interact through the NetworkTA, the list and contents of the threads are dynamic as they are continually updated.

In addition, the NetworkTA allows students and instructors to know who is currently using the system, so that participants can engage in a more synchronous discussion which can be useful for group projects. In this way, students can use the NetworkTA for collaborative projects where a group can coordinate plans and share ideas.

Physics and Chemistry

Professors Alfred Hubler, Barbara Whitmarsh, and Susan Arena manage the CyberProf software package for several physics and chemistry courses at the University of Illinois. In these courses, CyberProf provides students with online lecture notes and homework problems. Students complete homework assignments online and receive instant feedback upon submission of their homework. CyberProf intelligently analyzes the students' answers, reports specifically what is wrong with their answer (if their answer is incorrect), and allows them to try again. Even so, students can have difficulties with homework assignments. Additionally, concepts presented in class may not be clear to the students.

For these courses, messages on the NetworkTA are posted and threaded in the same manner as described for the economics course. However, the fashion in which students, online tutors, and course directors use the NetworkTA can vastly differ. Here, the NetworkTA serves as a forum for participants to pose questions about the homework and concepts presented in class and to reply to other previous questions.

Participants have customized NetworkTA sessions. New messages posted since the participant's last session are indicated by a prominent "Updated" icon next to all the discussion boards containing new messages. This makes it easier for students, online students, and course directors to find the messages they need to read in order to be up-to-date. Online student tutors and course directors are further aided by a "New" icon next to all discussion boards having threads which require attention [Fig. 2].

To find specific content in the current list of threaded messages, participants can enter keywords to search for messages containing those keywords. For example, a student preparing for an upcoming exam needs help with kinetics. The student can perform a keyword search on the word *kinetics*. The NetworkTA will display all the

BEST COPY AVAILABLE

threaded messages containing the keyword *kinetics*, and the student can read homework and lecture questions regarding kinetics.

The NetworkTA is used in conjunction with CyberProf to help students understand conceptual and practical difficulties presented in the lecture, online homework assignments, and the textbooks. Students who have successfully completed the course the previous semester are paid to teach and to respond to online questions presented by current students. The hours served by the online student tutors cover most of the day, seven days a week. Interaction through the NetworkTA can develop psychological resonance among students. Because the online student tutors are students themselves, students currently in the course are apt to ask questions and share statements more freely. Also, the online tutors relate more closely to students and communicate in less complicated terms so that students can understand.

Students have access to online tutors, graduate teaching assistants, and course directors during most of the day. A student can come in contact with other students online, some of whom they might not meet in the classroom. Course directors may monitor activity on the discussion board and can join in the discussion. This would not be the case in the classical educational environment where outside help is commonly obtained during fixed office hours and where interaction with classmates may be limited.

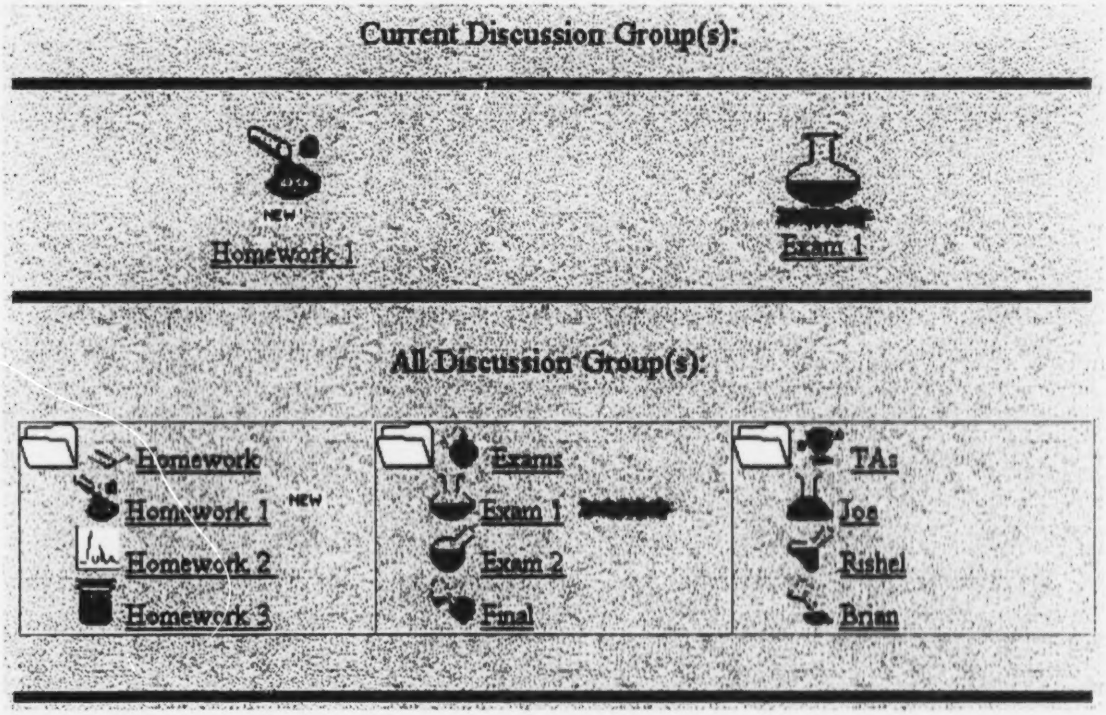

Figure 2: The NetworkTA Navigation page displays the currently active discussion boards prominently at the top of the page above the list of all discussion boards. Also, the organization of the discussion boards in the conference is represented in a tree structure consisting of folders and discussion board icons.

Biology

Professor Deanna Raineri, the director of biology's CyberProf website at the University of Illinois, uses CyberProf and the NetworkTA in the same manner as the course directors in physics and chemistry. Students complete homework assignments online using CyberProf and interact with other students and the course director through the NetworkTA. Customization of the NetworkTA by this course director illustrates the flexibility of the conferencing system. Customization allows course directors to create an environment which best fosters enthusiasm and effort for learning the course material, allowing natural resonance among conference participants to occur.

BEST COPY AVAILABLE

Through customization, the instructor modifies the NetworkTA's interface to facilitate student usage and to improve student interactions.

The NetworkTA consists of several logically different components, all of which are easily customized from the password secured Director Options menu. The Navigation page displays the available discussion boards and the organization of the discussion boards. The Message List page lists all the threads in a discussion board. The Word Search window provides a simple menu to display messages containing selected keywords on the Message List page. The Log of Users page publicizes a registry of current NetworkTA participants. The Compose New Message page allows participants to initiate a new thread in a discussion board. The Read/Reply Message page displays the contents of a posted message and permits the participant to respond to the posted message. The appearance and function of all NetworkTA components are determined by the course director. Many pages include director defined page headers and footers which can serve a variety of functions ranging from general announcements to special instructions. Often, these include a banner, links back to the course homepage, and links to other related Web sites.

The NetworkTA offers a simple installation procedure for the director to setup the initial framework. From the beginning, it is essential that the initial setup does not intimidate or discourage the course director. A course director who is enthusiastic about online conferencing will encourage teaching assistants and students, and can influence the degree to which teaching assistants and students get involved and interact. The initial installation includes creating the structure and determining the content of the discussion boards. After the initial setup, a more in depth installation can be made to further customize the NetworkTA.

To simplify use of the NetworkTA by discussion participants, the director defines a subset of all discussion boards to be the currently active discussion board. This subset is physically separated from the list of all discussion boards to allow easy selection. This can be seen in [Fig. 2]. In this way, participants can easily find the discussion boards that they should probably be using for that day. This is done by assigning each discussion board a starting active date and an ending active date. The NetworkTA compares this information to the current date and assigns the active discussion boards to be the current discussion boards.

Because participants are constantly contributing to the discussion boards, the list of messages within a discussion board is always growing. While waiting for a response, the participant will not be left staring at an empty screen until a new message appears on the page. The course director, upon installation of the NetworkTA, can customize an audio cue to sound the arrival of a new message.

For the most part, messages in the discussion boards contribute to the topics chosen by the director but there are instances when they may not. A participant may post an offending remark in a discussion board. A student taking an early final examination might post some of the questions to the final on the NetworkTA before the rest of the class has taken the exam. In such situations, the course director can selectively filter inappropriate messages so that participants will not read them.

Results

Examples of the NetworkTA used in courses at the University of Illinois at Urbana-Champaign provide insight into the different roles of the NetworkTA and how it interfaces students with other students, online tutors, and course instructors. Most of the features in the NetworkTA have been created as a result of the goals of individual course directors. Course directors have found that the flexibility in customizing the appearance and function of their version of the NetworkTA has been invaluable. The NetworkTA has provided students with better access to instructors and other students.

Currently, several institutions are using CyberProf and the NetworkTA including the Bradley University, Wayne State University, George Mason University, Universidad Nationale Autonomade Mexico, Purdue University, University of Illinois at Urbana-Champaign, Parkland College, Urbana High School, and Homehi. In addition, other courses at the University of Illinois also use CyberProf and the NetworkTA. Course instructors and online tutors for some courses use the NetworkTA to respond to student questions related to homework, laboratory exercises, exams, and course administration. In other courses, students engage in online discussions and exchange ideas about course related topics, mediated by the course director. The NetworkTA becomes a platform for students to develop arguments on "paper" and to receive feedback from the instructor and other students. As a whole, the reaction to the NetworkTA from course instructors has been highly favorable.

Future Work

The NetworkTA is continuously updated with new features as the growing needs become more apparent. Feedback from student evaluation committees and course instructors will continue to play an important role in the development of the NetworkTA. While the NetworkTA presently has much to offer as a medium for collaboration and communication, many new features are still in the works. The uploading of sound, image, and video information from the client machine to the CyberProf server will add interactive multimedia and enhance interaction among NetworkTA participants. Communication through the NetworkTA will be improved using WebDraw-WebPlot, CyberProf's online whiteboard. For courses which also use CyberProf to assign homework, requests have been made to allow online student tutors to view the homework solution to the exact problem assigned to a particular student through the NetworkTA.

Acknowledgments

The development of CyberProf and the NetworkTA is carried out at the Center for Complex Systems Research at the Beckman Institute of the University of Illinois at Urbana-Champaign. It is supported by a grant from the Department of Physics.

The NetworkTA owes a great debt to Joe Libson for his insight and Perl expertise, C. K. Rishel for oversight and direction, Andy Assad for his useful discussions, and Brian Rogers for system administration. The feedback from many of the UIUC faculty members involved with CyberProf and the NetworkTA including Barbara Whitmarsh, Susan Arena, Deanna Raineri, and Jane Leuthold, led to many improvements and added greater functionality. Their suggestions were greatly appreciated.

Abstract: At present, facilities allowing users to add structure and content to existing Web documents are scarce. From a usability view, bookmarks and cookies are useful tools allowing users to define some measure of conceptual structure to a set of documents. In the educational context, creating an evolving, user-created concept structure is an important component to support learning as concepts are actively organized and re-organized. The Dynamic User Searchable Index Engine (DUSIE) provides facilities for users to define supplementary links within and across Web documents using existing content to create a link metastructure and to add new content through annotations. In the student-centered electronic learning environment in which the system is used, DUSIE provides a means to augment existing content material with a student-created view of concepts.

Introduction

The dramatic growth and widespread acceptance of the World Wide Web provides open accessibility for an unprecedented amount of information. The promise of Web-based hypertext documents lies in the ability to produce complex, richly connected and cross-referenced bodies of information. However, the documents can become a system of tangled webs confusing both author and reader. This is primarily because the most widely used tools for accessing Web documents provide neither a sense of the overall relations of documents nor facilities for the user to impose a structure unique to his or her view. In the Web hypertext there are no simple organizational schemes, such as page numbering, that can serve as ubiquitous and commonly understood paradigms of navigation and location. In particular, the static nature of HTML documents and relatively limited indexing and navigation mechanisms of the most widely used browsers do not realize the potential for general hypertext systems. Facilities which support users in creating alternatives to the static link structure of Web documents are not in general use.

Augmenting Web Structure for Learning

The restrictions of most Web systems are particularly limiting in educational environments. Nuthall and Alton-Lee [Nuthall and Alton-Lee, 1993] suggest that as students are involved in activities about a topic, they store a representation of the information about the topic in their working memories. These representations become connected and integrated with other related information about the topic in semantic memory - a schema. Representations which do not get connected to the existing infrastructure are lost. If, however, enough representations are integrated and connected, the ideas become established in long term memory. Sometimes, however, information is misinterpreted and reorganization is required.

A similar thread underlies the learner centered principles set forth by the American Psychological Association Task force on Psychology in Education [Presidential Task-force, 1993]. Learners seek to make sense out of what they are given, no matter what the quality or quantity. At times this leads to misconceptions, but these must not be discounted in the effort to achieve deeper understanding as learners link new knowledge with old knowledge. Furthermore, metacognitive abilities should be fostered in the learning environment.

Multimedia presentation techniques, including web-based computer aided instruction, have been applied successfully to support or enhance learning environments. Success in these environments is often attributed to the engagement of the student in an active learning process. Student's efforts to understand are placed at the center of the educational enterprise and emphasis is on the student's construction of knowledge. However, Weingrad et al. [Weingrad et al., 1993] point out that all too often the use of multimedia in the learning environment is an interactive activity for the author through the explicit definition of concepts and links, but remains a rather passive activity for the student user. Still, this passive activity can have a significant impact on student understanding based on the supposition that an implicit ordering and reordering of the information occurs.

Facilities supporting active engagement by hypertext readers are among the functions characteristic of second-generation hypertext systems, facilities not yet in widespread use in the Web. In describing issues to be addressed by hypertext systems Halasz [Halasz, 1988] identifies both dynamic, or virtual, structures and extensibility, or tailorability, as important components. Users should be able to move through the system according to their needs without spatial or conceptual disorientation. There should be facilities for annotation and placemant of bookmarks or creation of indices. Facilities providing these functions would allow users to more effectively accomplish tasks and would support the learner in overcoming many of the limitations of hypertext as a medium for learning.

Current navigation and bookmark facilities for the Web

Current facilities supporting the organization and retrieval of information contained in web documents are in practice extremely limited. Bookmarks are perhaps the primary tool in widespread use. When adding a bookmark, the address of the document is initially added to the bottom of a list, and perhaps later manually placed in a hierarchy. The bookmark then points to a document, rather than directly to the area of the document containing the point of interest. Retrieval of the associated information is as simple or difficult as viewing the list or hierarchy, selecting the bookmark, and then going to the document to continue the search for the item of interest. The context of the bookmark is removed from the original intention. Clearly, bookmarks are not enough.

There are many ways to navigate through web-based documents using current browsers, including hyperlinks, menus, toolbar buttons, location boxes, and directory entries. However, most facilities require users to have knowledge about the location of the information, rather than supplying facilities for content-based access. Sites on the Internet can be saved and revisited, but the focus is the page or site, rather than the content or even exact location. Therefore, users often must continue the search for the desired information even after following markers they have set.

This sort of location-based navigation, browsing, and information retrieval is effective for small hypertext systems, but for large hypertext database systems like the Web, information retrieval through navigation and queries becomes crucial. This is particularly true when the user is in an educational setting and searching to find and organize new information. Content search techniques can be extended to web documents [Beeri & Kornatzky 1990]. All nodes and links can be treated independently and examined for a match to a query. The use of structural queries has also been suggested where specifying terms are used to retrieve edges, paths and cycles. The set of elements retrieved is collapsed into a hypertext network and users can incrementally compose queries.

Another type of content-based structuring of hypertext document content was suggested by Bruza [Bruza, 1990]. The approach uses a two-level architecture for hypertext documents where the top level "hyperindex" contains index information and the bottom level "hyperbase" contains content nodes and links. The hyperindex consists of a set of indices which are themselves linked together. When an index term describing the required information is found, the objects from the underlying hyperbase are retrieved for examination.

A Hypertext Environment for Learning: PDP

The Programing Design and Programming (PDP) project [Fowler & Fowler, 1993] focuses on developing and implementing a student-centered virtual classroom for introductory computer science courses. PDP incorporates courseware and tools that create a student-centered learning environment to develop a life-long learner skilled in information access and utilization. The virtual classroom centers on an integrated set of software tools: 1) hypermedia notebook (PDP "text book") with class notes, executable examples, assignments, etc. 2) a pedagogic computer aided software engineering (CASE) tool, 3) an algorithm animator, 4) a programming language facility integrating editor, compiler and debugger, and 5) news group and e-mail facilities to support electronic collaboration and mentoring. The structuring of student activities through laboratories and electronic communication is designed to support the student by creating small scale communities of learners in which to work [Fowler & Fowler, 1996]. Students have an opportunity to express themselves via multiple paths - program design, programming, and writing to enhance their problem solving skills.

The extensive use of electronic tools is natural in the discipline and has allowed us to develop this rich and interactive suite of tools to enhance both the learning and the teaching environment. The PDP hypertext, CASE tool, and algorithm animator allow us to present ideas visually and interactively in an environment that facilitates experimentation. Students use the hypertext as a scaffolding to organize concepts and explore the knowledge base, while completing practical work using tools that are relevant in the real world. The supposition is that the user gains understanding through the exploration and implicit ordering and reordering of the information by actively interacting with the hypermedia, and through the transfer and transformation of information from one tool to another.

A Tool for Ordering Content and Creating Structure

Though the tool intensive and highly integrated PDP virtual classroom provides a rich assortment of resources to support information retrieval and understanding, the original tool set did not include a tool which facilitated the capture and organization of meta-knowledge about the resources, particularly the hypertext documents. Supporting the idea that it is the user's perception of the concept structure that is important in the learning environment and the ability for the user to organize their concepts as they perceive them, we have developed a set of tools with which the user is able to construct a personal repository of concepts and concept relations to complement the author centered document structure. As an extension of the virtual classroom, the tools reinforce learning through the active construction of an associative network of terms and annotations. Students explicitly define their understanding of the concepts by creating an index into the hypertext document. They impose their ordering on the concepts and modify their ordering as their perceptions of the concepts change. The tools provide facilities to move through hypertext documents, construct a network of associated concepts, annotate the document, and modify the user-created index as appropriate.

This user-created dynamic open indexing system, which can connect to other information resources and allows individual annotation, provides the sort of functionality suggested above for augmenting Web structure. The goal of the user-created index is to reduce cognitive overhead by allowing users to define an index using their own terms, based on their understanding. Each index term contains semantic information relevant to the user. The indexing system keeps track of nodes and links to conceptual materials, thus providing a navigational tool through conceptual space. With its additional ability to cross-reference, the index is often more relevant to the user than an index created by the author. The tools are introduced in conjunction with the virtual classroom and the associated hypertext document. Yet, they are not limited to use in that environment. The user can integrate materials from any other web based hypertext document, as well.

DUSIE Searchable Indices

In the simplest terms, the Dynamic User created Searchable Index Engine (DUSIE) provides users facilities to construct an index for Web documents. Users define a list of index terms, make annotations to the terms, and link related concepts. In the context of the educational setting in which DUSIE was developed, a primary function of the indexing process is to provide a set of terms for each document that reflects the user's conceptual domain and can be used efficiently and effectively to retrieve information from the document. More generally, the system's functionality supplies mechanisms to create 1) new nodes through the annotation facility, 2) links to points in existing Web documents for the new nodes, and 3) alternative links for existing Web nodes through the addition of terms linked to points in existing documents.

Creating the Index

While Web documents use a static and explicit model of hypertext, i.e., nodes, links, and link markers are fully enumerated during creation, DUSIE allows the user to create a virtual structure or model of hypertext through a user defined indexing scheme. The virtual structure, or user defined index, has two levels: the index term level with annotation capabilities and the hypertext base level [see Fig. 1].

The index is made up of a set of index entries. Each index entry consists of a term descriptor or keyword supplied by the user, a locator (like an HTML anchor), an annotation area, and a set of related term descrip-

BEST COPY AVAILABLE

tors. The term descriptors are as general or as specific as desired by the user. Any particular index term provides a focus for the set of related concept descriptors and so a broadening or refinement of the concept represented by the focus index term. The focus term and the set of related concepts then creates a structure that can be used to support query by navigation. In turn, these indices provide immediate access to required information without navigating through the document space.

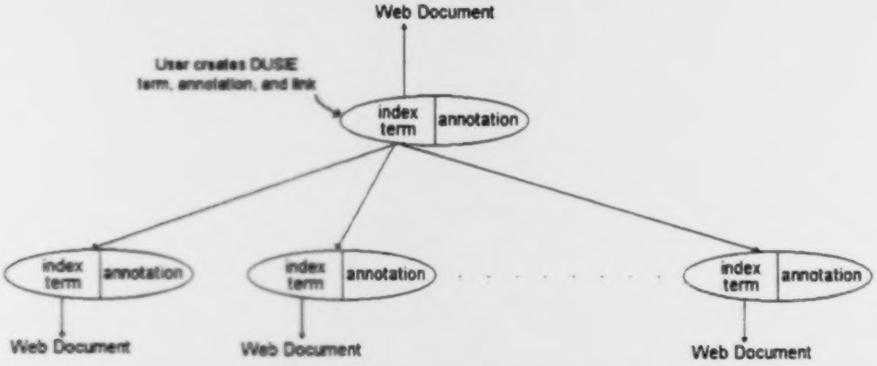

Figure 1. User-created DUSIE links and nodes supply annotations and connections to Web documents. DUSIE nodes can have multiple targets through additional terms linked to a node.

When using DUSIE, an index term is first defined by the user, and a new index term node is created and inserted into the index level. A link is made from the new node to the location in the hypertext document specified by the user. The node is also linked to an annotation block, providing space for the user to make an annotation about the term. After a new index term is defined, the user can define relationships between the index term and other index entries. If a relationship is defined, a link is created from the focus index term node to the related entry node. This creates a set of index entry nodes linked together. The assumption is that the links are created because the user perceives a relationship between the index terms represented by the nodes. As the user's perception of the concept materials change, the user can modify the index term network by adding or deleting links between nodes. These user defined relationships among entries serve somewhat as a user defined thesaurus of index terms, even though the terms are not distinguished as synonymous or subordinate, rather just as related concepts. This facility allows the set of index entry nodes to be used later in navigation through the hypertext, as well as for more explicit retrieval of information.

The user can make an annotation for each term entry in the index. The annotation might contain explanatory notes, materials to extend the original document content, or even a part of the actual document text. The annotation can be modified at any time as users' knowledge or perceptions change.

Though the indexing scheme incorporates a two level model, the implementation of DUSIE uses a three level architecture: information source (database), index application which creates the user defined conceptual structure, and user-interface client (Java virtual machine). This architecture was chosen to simplify modification of system components, particularly the user interface. The database stores the user created index structures on a file server. The index application retrieves information from the database and creates the user defined structure, while Java and Javascript are used to support the user interface.

From the user's perspective, the Java-based application looks and feels as though it is a part of the PDP hypertext document. Upon invoking the index option from the PDP hypertext document, the applet is downloaded and the application executed. The user's information is retrieved, the index structure is created and finally the user's index and the commands to modify, save, and exit the indexing engine are displayed.

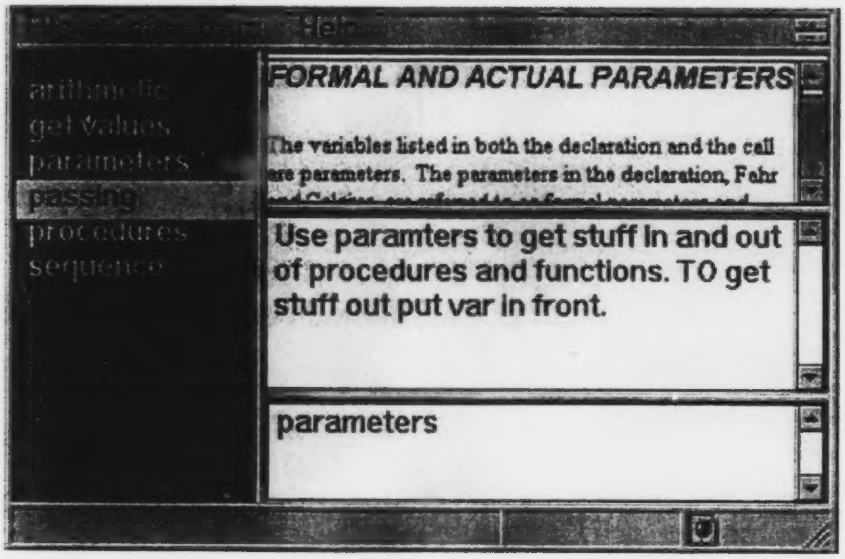
A Query Tool for Information Retrieval

DUSIE provides content retrieval in a manner similar to Bruza's two-level architecture for hypertext documents through a top level index information and a bottom level containing content nodes and links. In the DUSIE implementation the hyperindex is a set of indices linked together. When an index term describing the required information is found, the objects from the underlying hypertext document base are retrieved for examination.

Retrieving information in this manner is retrieval through navigation. After selecting an index term, the information associated with the hypertext base link is displayed in the browser. The annotation can also be displayed in the browser. Information may also be retrieved using the related concepts entries, facilitating the retrieval of semantically related materials. The user can move directly to the desired information as well as access related information without having to remember locations, links or other structural details. As a reflection of the users conceptual domain, the index terms might be considered metanodes which are linked to other metanodes via terms in the related concepts term set. In this way the index system expresses local relations among clusters of nodes.

Using the System

One way to get a feel for the system is to walk through a sample session using the system. Typically, the user is working in the distributed environment, and has a number of windows open on the screen. One of the windows contains a web browser opened on the web based courseware. From the main table of contents of the course's PDP hypertext, the user invokes the index by submitting their account name and password. A Java applet is downloaded and executes the index application. Upon verification, the user's database is retrieved from the file server.



FORMAL AND ACTUAL PARAMETERS

parameters

Figure 2. PDP user index window displaying index terms, hypertext reference, annotation, and related terms for a user defined index.

The user defined index structure is displayed in the PDP - User Index window [see Fig. 2]. The display window contains five areas: the menu, the index term list, linked hypertext, annotation, and related concepts list. The menu provides commands to add, annotate, add related concepts, delete, save and close the index. A list of the user's previously created index terms are displayed in the index term window. The user selects a term from the index list to view the indexed area in the courseware. The area of the hypermedia document referenced by the index term is displayed in the text frame of the window. Any associated annotations are displayed in the annotation area of the window, and terms designated as related terms are displayed in the related terms area of the window. The commands available from the edit menu allow the user to enter new terms into the index, modify their annotations, and link related terms. By choosing from the related concept list for an index term, the user can use the index as a navigational tool through hypertext documents.

Prototype Graphical Interface

With increasing use of visualization techniques in the presentation, retrieval and navigation in information spaces, a prototype graphical interface is under construction. The principle visualization is a network display based on the user constructed set of index terms and related concepts sets. Index terms are viewed as nodes in a network displayed in three dimensions using tools developed for general display of Web document relations [Fowler et al., 1996]. User defined relationships between nodes appear as edges. The nodes and edges in the visualization provide information about the user's perception of the document information and their imposed ordering. The nodes in the network represent entries in the index set while the edges represent links to related index terms. Since perceptions change, a critical component of the network visualization is the ability to modify the structure of the relationships by adding to, deleting from, and modifying the existing edges. The visual environment also supports exploration and retrieval of information. Given that a node represents an index entry denoting a particular concept, the material can be retrieved or other related concepts can be retrieved by following links in the term network display.

Conclusions and Future Directions

DUSIE provides tools allowing the user to create, modify, and save an annotatable index for web documents. This functionality allows the user to create user-centered semantic networks of document concepts to complement the author-centered structure. In essence, users are able to construct their own extensible hypertext which constantly evolves as their understanding of the subject matter and need for information evolves. The students' index structures maintained by the system provides a source of information about the students' perception of relations among concepts. The ways in which our perception of the structure of the course content differs from that of students may suggest ways to modify content, documents, and pedagogy.

Abstract : This paper suggests using a hypermedia learning system which has the ability to extract intelligent instruction on the world wide web. The proposed system is designed for supporting individual instruction on the web. The system is composed of expert module, student module, instructional strategy module and network interface module. To implement this system on the world wide web, we use CORBA-based CGI application for user interaction. To diagnose students' responses and generate evaluations, we use several linguistic variables.
The advantages of using this system are intelligence and distribution of resources. Intelligence of the system is dynamic generation of problems and the ability to provide a dynamic instruction strategy. In addition to showing instructional unit network and students' learning paths, we can overcome disorientation problem that have frequently occurred on the web. We use CORBA to overcome the disadvantage of WWW, passive protocol, HTTP.

1. Introduction

The WWW(World Wide Web) has been spread world-wide as a standard of distributing multimedia/hypermedia information. There are many applications based on the WWW, such as video on demand, distance learning, home shopping, and so on[Kappe 91]. The advantage of using distance learning on the WWW is apparent. We can provide instructional information using a hypertext form, the same as students' cognitive structure. Many studies in progress have interactive instruction made achievement[Dwyer et al. 95, Ibrahim & Franklin 95, Carver & Gregory 95]. Distance learning is available by exchanging instructional information via network among students and instructors at a distance. But WWW users ask for many extensions : integrating new kinds of web resources, extending web browsers, changing stateless web protocol. These problems can be overcome with a uniform model of resource interfaces, and transportable front-ends, that could be generically integrated in WWW. A uniform paradigm to encapsulate and structure web components can be achieved thanks to the OMG(Object Management Group)'s CORBA(Common Object Request Broker Architecture)[OMG 95].
Despite the WWW is able to access distributed information and services on Internet, it does not present individualized information to students[Jonassen & Mandl 90]. In addition, unlike existing stand-alone ITS(Intelligent Tutoring System)[Yoon & Wang 94], students must have the ability to study freely and search related information easily. Therefore the system must overcome potential disorientation problems[Kappe 91] that could burden accessibility.
In this paper, we suggest an intelligent hypermedia learning system that can make intelligent instruction and individual instruction on the CORBA/WWW. Our system can support concurrent learning and dynamic lesson planning for each student by using linguistic variables[Yoon & Wang 94]. In addition, our system provides instructional units in which students' response are diagnosed, and compared, thereby allowing dynamic instructional strategies to develop in step with the students' progress.

2. World Wide Web for ITS

In this chapter, we survey the merits and the defects of the WWW as an environment for ITS, while examining ITS' present approach on the WWW.

BEST COPY AVAILABLE

There are several merits to using the WWW for the environment of ITS. It is possible to study in a human way when the ITS is implemented on the hypermedia based on the WWW. Also, it is possible for many students to share the same tutoring material on the WWW. The growth of web sites has also given the student the opportunity to utilize information from all over the world[Lee et al. 97].

However, several problems do exist when using the WWW as an instructional device. Due to the limitless nature and sheer size of the WWW, it is often difficult to verify or diagnose a given student. The disorientation resulting from the great vastness of the WWW must also be overcome. In addition, students have difficulty obtaining the overall courseware structure of the ITS on the WWW.

CALAT is the present ITS on the WWW[Nakabayashi et al. 95]. This ITS is composed of the WWW and an individual tutoring system. In CALAT, the developers intended to solve the student verification, diagnosis and disorientation problem on the WWW. Using CALAT, an expert module decides the instruction path in order to prevent the disorientation. This decreases the effect which can occur while using the vast WWW for tutorial material. However, CALAT developers utilized their previous stand-alone ITS which suffers from heavy user loads as well as recognition loads due to the vastness of the WWW.

In this paper, we describe the design and implementation of a hypermedia learning system with intelligent factors. This suggested system can support concurrent learning, dynamic lesson planning and individual instruction for each student. Our system can provide the various path to the students so as to utilize the educational merits of the WWW. When a student becomes disoriented, our system provides advice to the student. We designed our system as a multiprocessing system so the loads of our system can be reduced when there are many students connected to our system. Finally, we provide the overall courseware structure to the students so as to reduce the recognition loads of students.

3. Design of the System

[Fig. 1] represents the configuration of the intelligent hypermedia learning system. This configuration, similar to a stand-alone ITS, is composed of the expert module, student module, and the instructional strategy module. In addition, our system includes the HTTP demon and CORBA-based CGI(Common Gateway Interface) application for the interaction between students and the student module, and IIOP to HTTP Gateway module for transmitting HTML document to student.

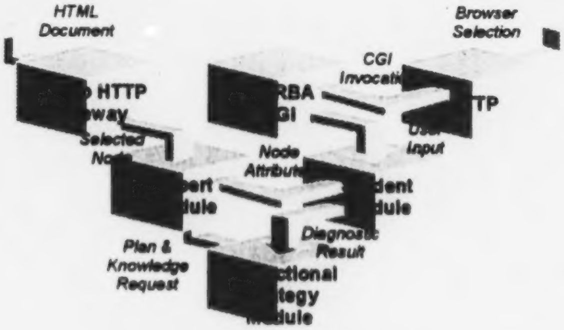

Figure 1: Configuration of system

In our system, many students can learn within the provided courseware. Student module diagnoses, infers learning state of present student according to the student database which store the information of each student. By using this diagnosed result the student instructional strategy module decides the next lesson, and transmits the courseware in HTML form. Thus the individual learning can be provided.

The courseware which exists in the WWW is transmitted to the student through IIOP to HTTP Gateway, then sent to HTTP so that the students can learn by using general WWW browser. Student module uses CGI application in order to receive the data for learning because the standard HTTP cannot receive the input of the user. All the input of the student is collected through the CGI application. And this information would be used to decide the instructional strategy.

BEST COPY AVAILABLE

3.1 Interface modules

Our system use the CORBA ORB and the CORBA CGI applications. Therefore, we need protocols, HTTP and IIOP. When a student selects some link, that selection send to HTTP demon using HTTP. Then HTTP demon invokes CORBA CGI application. The codes of CGI application are distributed over servers using CORBA object implementation.

During some object implementations are executed, the student module diagnoses student's selections. The student module sends diagnosed result to the instructional strategy module and current state of that student to the expert module. Then the instructional strategy module plans that student's next lesson. And the expert module selects appropriate materials and creates HTML document from them. This document the expert module creates, is not in web server machine. Because of that, we need some other method to send materials in HTML form to student's web browser.

The CORBA ORB uses IIOP, that we cannot use to send HTML documents to student directly. Then we implement the IIOP to HTTP gateway to distribute all the material and student information. The IIOP to HTTP gateway module converts protocol from IIOP to HTTP.

3.2 Expert module

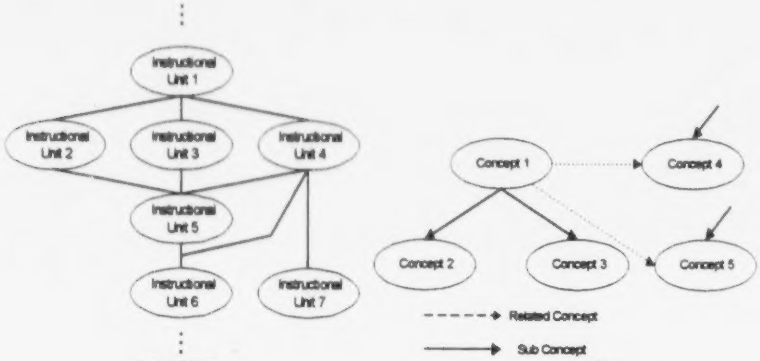
The domain knowledge will be used in coaching the students, diagnosing possible misconceptions after a student has made an error, and providing appropriate remedial materials. This domain model has dual representation network, the IUN(Instructional Unit Network) and the CN(Conceptual Network).

The IUN is a knowledge network which includes the materials to be shown to the student and the information concerned with learning sequence. The IUN is configured as a hierarchical network, and each node of it has the link to the subordinate unit and the subordinate unit denotes the prerequisite knowledge of the super unit.

Within the IUN, each node represents a learning unit, and it includes the theme of units, learning aim, the link of the concepts related to the learning units, the links to the problems, and the links to the subordinate units.

There are two types of the instructional unit. One is the explain unit, the other is the problem unit. The explain unit has instructional materials that have various media types such as text, graphic, still image, sound, and moving picture. The problem unit has two major concept to diagnosing the student's state, difficulty and importance. These concepts are used when lesson planning and gradual instruction objective creating. [Fig. 2(a)] represents an example of the IUN.

[Fig. 2(b)] represents an example of the CN. The CN is a knowledge network which piles up the knowledge of being contained in subject domain to be learned by the student. The CN is a data structure, which is a set of collected knowledge concerned with the declaring concept of domain knowledge, but independent upon the instructional knowledge. Each node within the CN represents the instructional concept, and the links between the concepts indicate the relationship of them. Using this relations, it is possible to generate problem dynamically, and to diagnose the student's error.



(a) IUN (b) CN

Figure 2: Examples of the IUN and the CN

According to environments of the CORBA, expert module can access CORBA ORB(Object Request Broker) to assist easy retrieval of materials, and URL indexing and caching demon to improve performance of system.

BEST COPY AVAILABLE

Unlike existing stand-alone ITS, user verification have to be supported so as to provide the individual learning according to the rate of each student. But HTTP can't support the method of user verification. When the first node is transmitted to the student, student account and password which are transmitted to the authorizing processor is transmitted into explaining node as a hidden tag. When the student requests the next node, the system can verify the students by the student account and password tag which are transmitted to student module.

3.3 Student module

This diagnostic result generated by student module is used by the instructional strategy module in order to inference the basis for determination of learning progress, supplying advice, and selecting comments.

In this paper, the student module is based on the overlay model. The student's knowledge has been learned is saved at the database within the student module, and the learning path can be shown in parallel with the learning achievement. As the learning proceeds, the student knowledge network in the database has the network form which is similar to the IUN as a knowledge base of the expert system. The diagnostic results of the student, problem type, and examples are saved at nodes in the student knowledge network. And the form of student knowledge network represents the learning path.

When the domain knowledge expert constructs the IUN and the CN by means of authoring interface, the two networks contain slots represented by linguistic variables for holding importance and difficulty which are the attributes of each problem and instructional unit. The linguistic variables used in input are shown in [Table 1].

Table 1: Linguistic Variable for Diagnosis

	Instructional unit	Diagnosis result
difficulty	D, M, E	G, M, B
importance	I, M, Ni	
modifier	[Very]*, [Less]*	

* where D = Difficult, M = Medium, E = Easy,
I = Important, Ni = Not Important, G = Good, B = Bad

The linguistic variables about the problem are used for diagnosing student's response. Using the linguistic variables, the domain expert can input at more user-friend environment because of being able to use linguistic variable and no need to decide special real number for attributes of all learning elements. The linguistic variable is the kernel of fuzzy theory which makes use of the fuzzy representation of human-being in computer. Using the concentration and dilation in the fuzzy theory, we can define the function which diagnoses the student's current knowledge. The function of concentration and dilation are as follows.

$$CON(A) = A^2 = \sum_{i=1}^{n} \{x_i, m_A(x_i)^2\}, \forall x_i \subset U$$

$$DIL(A) = A^{\frac{1}{2}} = \sum_{i=1}^{n} \{x_i, m_A(x_i)^{\frac{1}{2}}\}, \forall x_i \subset U$$

The membership functions upon Good, Medium, and Bad may be changed by the author, and the diagnostic results can also vary according to the membership function applied. Hence, the author can control the diagnostic results by changing these three membership functions.

The difficulty and the importance of [Table 1] are defined as the dilation of Medium(the default membership function of M is M=x), and both Easy and Not Important are defined as the concentration of Medium.

$$D = I = M^{\frac{1}{2}} = DIL(M)$$

$$E = Ni = M^2 = CON(M)$$

Therefore, we can define the DV(Diagnostic Value) function as follows.

$$DV(R_{1-n}) = norm\left(\sum_{i=1}^{n} (R_c/R_n)^k\right)$$

norm : normalization function that makes the result in the range of [0,1]
R1-n : The problem from start to n that was responded by student.
Rc : The number of correct answer according to linguistic variable
Rn : Total number of problems presented to student
k : The number of powers according to linguistic variable, defined as follows: I or D : ½, M : 1, Ni or E : 2

Normalization is defined as follows: suppose that all problem is correct, then, calculate the DV and divide into the result of calculation about correct answer. If the importance and the difficulty are applied at the same time to the same problem, select one that minimizes the membership degree and applies it.

To use more various values for representing the importance or the difficulty, we must consider modifiers applicable to the linguistic variables. In this paper we define two modifiers, Very and Little, as follows

$$V^nD = M^{\frac{1}{2^{n+1}}},\ L^nD = M^{\frac{1}{n\sqrt{2}}},\ V^nE = M^{2^{n+1}},\ L^nE = M^{n\sqrt{2}}$$

The equations above always hold the relation

$$V^nE \le L^nE \le M \le L^nD \le V^nD \quad (n \ge 0)$$

regardless of its number of repetition. Hence, the inconsistency of diagnostic result caused by repeated applications of the modifier is removed. For example, Easy is never less than Very Easy in spite of the number of Little modifier's applications.

The calculation result by DV function for the diagnosis of student's response is a real number which ranges between zero and one. To execute fuzzy inference using linguistic variable, result obtained by the DV function has to be fuzzified. Fuzzified result is one of the linguistic variable that consists of Good, Medium, Bad, and the modifier [Very]*, [Less]*.

If we fuzzify the diagnostic results into the linguistic variables, then they can be used together with the inference rules using the linguistic variables. [Fig. 3] represents the district graph of diagnostic value to fuzzify diagnosed result.

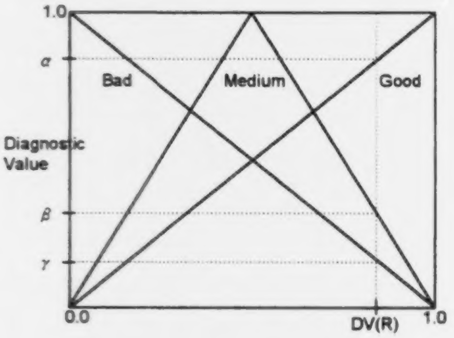


Figure 3: District graph of DV

If the author input the inference rule and there was conflicting among those rules, that is, different result is input at the same condition, the author is presented the condition and is asked what result should be used. The result of learning, whether well or poor, is determined according to what deterministic variable is input by the author. This shows that the author's intention is able to be reflected to inference rule.

3.4 Instructional strategy module

The instructional strategy module mediates and develops the learning of the students through the planning of a curriculum to order the domain knowledge that must be supplied to students, and the planning of teaching to decide the presentation method, re-planning to construct proper planning and monitor the action of students.

Among the contents of a lesson which are taught to the students, the total contents of a lesson are composed of the network of the main objectives of instructions that are relatively independent each other.

Lesson plan presents the evaluation problem and the instructional material of instructional unit, decided by the curriculum planning to students in the proper level. The Instructional strategy module offers students the instructional material on the instruction unit and the evaluation problem by means of the method divided by the curriculum planning.

The gradual instruction objective must be created by considering the student level that has acquired the degree of difficulty of instruction unit and students' records obtained previously. For an efficient instruction, problem presentation order must be planned dynamically by according to the students' level. The instructional strategy module can create dynamically the problem about the concept learning and the discrimination learning using the CN.

Also instructional strategy module can dynamically limit the number of links which the student can select, according to the level of each student. This module have functions which provide the students for advice when the students refer the irrelevant to the present learning content frequently or when disorientation problem occurs.

4. Conclusion

Existing distance learning systems has poor support for not only interaction with students, but also individual instructions. And researches that overcome disorientation problem in vast hypermedia space are very few. In this paper, we have designed and implemented intelligent distance learning system which supports interaction with students, can create dynamic instructional strategies. Our system consists of expert module, student module and instructional strategy module. Because our system has data structure and method that diagnoses students' knowledge, it is possible to plan lessons dynamically.

Student module can support interaction with students using CGI applications on the WWW, diagnose each student's knowledge using private student's information and students' response. In instructional strategy module, evaluation problem can be created dynamically according to the diagnosed result, individual instruction can be supported by deciding further instructional strategy. In expert module, student can recognize himself in courseware WWW on instructional unit network. So, we can overcome disorientation problem.

COMPUTER ASSISTED LEARNING IN CASE STUDY

Albert C.K. Leung and Frankie, C.B. Lo
Department of Computer Studies
Lingnan College
Tuen Mun, Hong Kong

Abstract: Case study is a well-recognized teaching and learning method, which has been extensively used in a broad range of fields, such as Information Technology, Operations Management, Business Process Re-engineering. However, many real world cases which are widely used in case studies are difficult for students to understand and to participate in the study, either because the information provided is too abstract, or not all students can join the discussion. Thus very often, in the limited study time, optimum learning results are not achieved. In this paper, we present a method to introduce Computer Assisted Learning (CAL) into case studies. The main objectives are to improve students understandings of a case, and also to increase the effectiveness and efficiency of their learning. Unlike traditional case study, the setting of our approach is mainly on one-to-one basis rather than in group. The initial evaluation of our approach is also presented in the paper, and the problems with many current CAL software are also discussed.

INTRODUCTION

Traditional teaching through lectures alone is no longer sufficient for good student learning. Teaching students especially in big class is not an easy task due to their different levels of learning abilities, and it lacks communications. In addition, certain aspects of subjects may be difficult for students to learn merely with lectures and textbooks. Therefore, lots of effort is usually required to smooth the knowledge building after lecture through tutorials or seminars.

To improve the quality of teaching and learning, many innovative measures have been introduced into traditional teaching method, such as radio, TV, and computer-assisted instructions. Especially in recent years, with the advances in multimedia technologies, many computer assisted teaching and learning applications emerged [Blevis 1991][Kass 1991][Edelson, 1993]. However, most of these applications focused on presentation of course materials rather than on mutual communications, and thus have little impact on the quality of student learning. A phenomena as pointed out by Adam [Adam 1993], "The content of instruction, not the means of its conveyance is what influences performance results." Such phenomena indicates that there is a lack of consensus on the essential architecture elements of an educational system.

Instead of setting our goal on building generic principles about the design of educational systems, in this project, we mainly concentrate on case studies, which are usually conducted after lectures. A case study normally involves more discussion, i.e. more interactions, than in a lecture. Thus, a successful educational model built on case study would be highly representative in building of an educational system for teaching and learning.

PROBLEMS WITH CURRENT EDUCATIONAL SOFTWARE

Schank [Schank 1993] explains that the dominant educational paradigm in computer based instruction has been what can best be described as "page-turning architecture," and therefore, they asked students to do little more than "press button for next page" for video or graphics. Such software shows no creativity in terms of innovative educational method, and exposes lack of understanding of the problems with current education system among those developers. This is in line with Scardamalia's comments [Scardamalia 1993], who says "Traditional knowledge reproduction strategies limited potential for advancing knowledge, and often are not even very effective for purposes of memorization and organization of knowledge." He regards that the most conspicuous failure of those educational software is in the development of understanding.

Creating educationally effective multimedia software means taking seriously the idea of learning by doing, and focusing on understanding and supported learning in entirely new ways, with vital attention to the skills of social interaction and participation. Pea [Pea 1993] points out, "In contrast to learning-before-doing, which is the model of most educational settings, learning-by-doing is a model in which learners are increasingly involved in the authentic practices of communities through learning conversations and activities involving expert practitioners, educators, and peers." Thus, good educational software is active, not passive, and ensures that users are doing, not simply watching.

CHARACTERISTICS OF CASE STUDIES

Case study is a well-recognized teaching and learning method, which has been extensively used in a broad range of fields, such as Information Technology, Operations Management, Business Process Re-engineering. A good case study would allow students to be inquisitive and effectively master the course materials through interactions and participation in discussions. Such practice has proved to be very successful in the past. However, there are also shortcomings. First, some real world cases are difficult for students to understand and to participate in the study, because the information provided is sometimes too abstract. In particular, for those cases which students are not familiar with, students can hardly understand them without showing them the actual settings. Secondly, in group study, not all students may join the discussion, especially those inactive students. Thus very often, in the limited study time, the optimum learning results are not achieved.

COMPUTER-ASSISTED APPROACH

In our Business Faculty, case studies are widely used in several major courses, such as Marketing Management and Information Systems Management. The initial development was concentrated on the course of Marketing Management. The software package developed at its current form is not only for case studies, it also can be used by students for course review, as it contains most of the course materials, though the emphasis was put on case studies.

There are mainly two innovations in our approach. First, multimedia technologies were used to present real world cases in realistic settings through computers. Such method can convey sufficient materials to students in comparatively shorter time. It also gives students a stronger impression about the settings, and thus allow them to be involved more actively in the study later on. Second, such case studies can be conducted on one to one basis, not necessarily in group, because the package was incorporated with questions, feedback, and suggested answers in multimedia form. By so doing, students will have the option of recovery from failure by asking persistent questions and mastering the material before moving on without embarrassment, thus individualized attention is achieved.

There were two main challenges encountered so far. The first challenge was to produce the video clips which show the real world settings of the cases selected. The second one was to prepare the anticipated questions which might arise and to have previously videotaped and catalogued the answers to these questions. Both of these issues are critical for the success of a case study software.

EVALUATIONS AND FURTHER WORK

The multimedia software developed has been used on trial by selected students for Beta test on an individual basis. The results of our initial evaluation were encouraging. In particular, the following features of our package were found very useful. First, the set of buttons, such as Why, How, What, Too Hard, No Way, and Boring, which allow a student to stop anything that is going on and find out what he/she needs to know, were very useful. Second, the difficulties of the questions provided were appropriate (only satisfactory answers will lead to the next session). Third, different methods of presentation of same materials for different levels of students, i.e. Hard, Medium and Easy, were helpful. Fourth, system logs to monitor the progress of students, in particular regarding poor performance records, is necessary.

Formal evaluation is yet to be conducted through interviews, questionnaires and analysis with both lecturers and students in order to refine the software. Then, a statistical experimental design will be developed to evaluate and compare the learning effectiveness of the traditional case studies and our new approach.

CONCLUSIONS

Through this research, it is intended to study whether computer assisted learning can be used in a highly interactive educational environment, i.e. case study. The main objectives are to improve students understandings of a case, and also to increase the effectiveness and efficiency of their learning. The initial evaluation of our approach was conducted, and the results were encouraging. In general, it has proved so far, computer assisted case study is possible. This research will also help us to build a common framework of an all encompassing task that achieve the optimum result of understanding, which incorporates the essential architecture elements that should be considered in building an education system.

Abstract: In this presentation, we report a study conducted with the practitioners in the multimedia industry on the design and production process they have used. It is our purpose to provide useful information on what the multimedia production process is, and how people in the industry design and produce multimedia programs. It is intended to inform interested people, especially students who want to take a career in multimedia, about how to get better prepared for the multimedia job market.

Rationale of the Study

We are experiencing dramatic changes in all aspects of our life brought by the advancement of technology. Technology plays a prominent role in determining what we learn and how we learn. New technologies such as interactive multimedia and telecommunication have revolutionized the process of information presentation and information construction. Multimedia programs have been developed and used in all content areas and at all levels of schooling. In the past few years, the use of multimedia CD titles have increased tremendously both in education and in industry [Lee, 1995]. With the popularity of World Wide Web, it is foreseeable that interactive multimedia technology will have more influence on the way we communicate information and on our learning.

The rapid growing market of multimedia has created a great need for multimedia designers and developers. Many multimedia companies have been formed, many college graduates have entered the multimedia business and many more students wish to become a multimedia designer or developer. Because the technology is relatively new and is changing rapidly, our understanding of the development process is still limited. Little was found in the literature on this topic. Although students at universities may gain a solid foundation in instructional design theories and technical skills in using technologies, the actual development processes for successfully producing an instructional program are not always readily apparent or accessible to students [Gentry, 1994; Greer, 1992]. There is often a gap between what is taught in an academic setting and what is practiced in the real-world. Students often lack the competence in professional practice which requires practical knowledge involving know-how and insight learned through practice [Quinn, 1994]. Therefore, students who want to enter this growing job market are often not well-prepared in that respect. How does the multimedia process work? How to design and produce a quality multimedia program? More importantly, how can students be better prepared for this growing market?

Purpose of the Study

The purpose of this study is to find out the multimedia design and production process from the practitioners, who are involved in it every day. Our research questions were:

1) How does the multimedia production process work?
2) What are the critical aspects in the multimedia development to ensure the quality of the programs?

3) What different roles do people play in multimedia development and the relationships of these roles to the entire process?
4) What can students interested in multimedia do to prepare themselves for the job market?

Method

To answer the research questions proposed, we sought to interview the multimedia practitioners who are involved in developing multimedia programs from Austin, Texas. Austin is known for its advancement in computer technology. It houses major technology companies such as Apple, Dell, IBM, MCC, Motorola, Samsung, and Texas Instruments as well as many smaller technology companies. Austin has a very active multimedia community which supports award-winning companies as well as start-up companies.

About Interviewees

We sought to interview those companies that were involved in developing educational multimedia titles in the Austin area. Ten companies were identified using a multimedia directory compiled by Texas Government office. Because our goal was to understand the production process for developing educational materials, we chose not to interview those companies that developed entertainment programs only. Fourteen multimedia developers with different backgrounds were contacted, and interviewed.

All of the sixteen interviewees were working on instructional and interactive multimedia projects at the time of the interviews. A number of the interviewees had contributed to award-winning multimedia titles. Eight were females and eight were males. They came from various backgrounds such as radio-TV-film, computer science, fine arts, physics, or instructional technology. Some had a bachelor degree while others had a master degree. All of them had years of experience in designing and developing multimedia products, and assumed different roles in their companies (i.e. the role of a project manager, an instructional designer, a programmer, a graphic, artist, an animator, a permission specialist, or a videographer). With their experiences and backgrounds, these multimedia developers were able to discuss the process of developing multimedia projects from several perspectives: (a) that of someone who oversees the entire process, (b) that of someone who is in charge of his or her department but reports to the project manager, (c) that of someone who plays a specific role in the entire process such as a permission specialist.

The Development of the Interview Questions

The four research questions formed the focus of our inquiry. Using these research questions as the starting point, we proceeded to develop a series of interview questions. The development of the interview questions was based upon the synthesis of the few published literature on the topic [Apple Computer Inc, 1994; Josephson & Gorman, 1996]. Initially questions on various aspects of multimedia were developed, which included questions on fact-checking, project management, authoring, programming, and graphics. Using these questions, three preliminary interviews were conducted with the multimedia developers from a medium sized company. The purpose of conducting the preliminary interviews was to confirm the importance and appropriateness of the interview questions, and to ensure the questions developed would help to answer the four research questions. Based upon the data gathered from these three preliminary interviews, the interview questions were revised and refined. The final interview questions consisted of questions on 12 aspects of multimedia production process: (1) general questions, (2) fact-checking question; (3) authorer questions; (4) permissions questions; (5) project manager questions; (6) programmer questions; (7) artist questions; (8) animator questions; (9) instructional designer questions; (10) writer/editor questions; (11) videographer questions; (12) audiographer questions. The number of questions within each aspect varied, ranging from three question in one aspect to 29 questions in another. Some sample questions included: What is role of your department in the multimedia process?, what kind of expertise do you look for in hiring new people for your department?, what are some of the major obstacles you face in doing your job?, How do you coordinate with instructional designers?, How do you acquire contracts? In what do you utilize user-testing?, How much of the screen do you reserve for text? When is voice-over utilized over text? and who is responsible for the script and storyboard of the video? The interview questions will be shared with conference participants.

Procedures

Once the questions were finalized, contacts were made with the potential interviewees in Austin area to find out if they were willing to participate in the interviews. We conducted the interviews with people who played different roles in the production process such as the manager, the programmer, the artist, the animator, or the videographer. A total of sixteen interviews were conducted from ten different companies. These interviews ranged from 15 minutes to 1 hour and 15 minutes in length with an average of 45 minutes depending on the available schedule of the interviewees. In addition to the specific questions regarding his or her role (e.g. animator), each interviewee was asked general questions such as the design and production process used in his or her company, the division of roles, important aspects and tips for producing multimedia. Interviewees were also asked to describe their professional and educational backgrounds.

Data Analysis

The interview data was first transcribed, then chunked, coded and categorized following Miles and Huberman's guideline (1994). A list of codes were first generated directly from the data. During the coding processing, the codes were refined, revised, and new codes for emerging themes were added. Patterns from the data were extracted and the relationships between the coded segments were compared and contrasted. The data was then sorted into categories and sub-categories according to their common themes and shared relationships. Finally the codes along with their themes were placed within the four research questions. Three researchers were involved in this data coding and analysis process. Each researcher independently coded the data. Disagreements among the researchers were discussed and resolved after reexamination of the data until a .98 interrater reliability was achieved.

Result and Discussion

Multimedia Development Process

The interview data revealed that the multimedia development process, though varied from company to company, consisted of these six main phases: (a) funding, (b) planning, (c) designing, (d), production, (e) testing, and (f) marketing (see Table 1). Each of the phases has a number of activities. The phases represented the process from the inception of an idea to the finished product. Very often companies worked on several projects simultaneously and usually the projects were at the different phases for a particular period of time. The project manager had the responsibility to ensure all people involved in the project to stay on task and complete their part by the specified deadline.

For the companies interviewed, most of the work was obtained through a contract from a client. The client could be a major publisher, a state or federal agency, or a company. They often obtained these contracts through submitting proposals to "Request for Proposals" sent out by the client [McDaniel & Liu, 1996]. Some work was obtained through personal contacts or the referrals by other companies. Obtaining funding was a critical phase for most small multimedia companies. Therefore, the interviewees stated that they took it seriously. They mentioned that producing quality work would help to establish their reputation so that the client may return the next time. Once the contract was secured, a series of negotiations began between the developer and the client. These experienced developers mentioned that it was very important to discuss the ownership of the content, the project schedule, and payment during the negotiation. Sometimes, the developer received the content from the client who owned the copyright and other times the developer had to generate new materials from scratch. The developer and the client also needed to agree on the completion dates for various phases to ensure the feasibility of the intended amount of work. The budget was also discussed at this point. A prototype was then developed to see if it would satisfy the client's needs. Based upon the client's feedback, various specification documents were developed which provided detailed information on content, design, interface, functions of the product. Flowcharts and storyboards were created to reflect the specifications. The production phase then began, which was followed by testing and marketing the product.

Roles and Responsibility

Developing a multimedia product called for creative work from many different talents such as a project manager, an instructional designer, an authorer/programmer, an artist, an animator, a writer, a videographer, an audiographer, a subject matter expert, and a permission specialist. The collaboration among these people contributed to a successful finished product. As the technology evolved, these roles within multimedia companies had been developed accordingly. Depending on the size of the company, the roles might be expanded into departments or one person might play more than one role.

Throughout the creation of a multimedia project, the roles within the company must be in constant communication in order to create consistency in the design and focus of the end product. The interview data showed that the project manager had the primary responsibility of negotiating with the client, and outlining the objectives, scope, schedule, and funding for the project. All different roles often provided their input into the vision of the project during the planning phase, which helped to ensure all roles had a central vision and were working toward a common goal. The expertise from the different talents was vital in determining whether certain design elements were feasible within the guidelines of the project. The instructional designers often assisted the project manager in creating specifications. Once the client and project manager agreed on the content and scope of the project, the instructional designer created storyboards or design specifications for the project. Most of the roles were involved in the production process. The artist was creating graphics, the animator was designing the animation, the writer was writing scripts, the videographer was collecting and digitizing video, the audiographer was casting, creating, or purchasing sound, the subject matter expert was checking the content validity, and the permission specialist was searching for and obtaining copyrights. As the production phase progressed, the authorers /programmers began to stitch together the elements of the piece and program the functionality of the project. Once the production phase was coming to a close, many of the roles remained on the project in order to revise the project based on client feedback, evaluations, alpha testing, and beta testing. After the production phase, the project manager continued to oversee the project, communicate with the client, and see the project to its completion.

Development Phases	Corresponding Activities
Funding	• writing proposals • responding to "Request for Proposals" (RFP) • writing grants • joining competitions • obtaining contracts through personal contacts, referrals, and demonstration of what one can do
Planning	• negotiating with the client on scheduling, budget, and scope • finding out what the client wants • brainstorming • deciding on the objectives, presentation styles, delivery platform • creating a prototype • getting feedback from the client
Designing	• creating documents specifying the design, content, function, interface • creating flowcharts and storyboards • creating timelines and identifying major milestones (deadlines for a particular phase) • distributing work among different roles (designer, programmer, artist, animator, videographer, audiographer, permission specialist)
Production	• programming • writing scripts • creating artwork • creating animation, video and audio • creating interface • putting together all pieces
Testing	• getting feedback internally • getting feedback from the client • getting feedback from users • revising and debugging
Marketing	• distributing the product

Factors Contributing to Successful Multimedia Development

Several factors outlined by the interviewees contribute to the success of a multimedia project. These factors are (a) constant and smooth communication among all people involved in the process, (b) taking advantage of all the talents, (c) continuous evaluation and feedback, and (d) on task and on schedule. Because multimedia development involved many different roles. Communication among all parties involved was important. Most interviewees mentioned that they maintained weekly meetings among the team and regular informal conversations. Such constant communication between each other helped to keep everyone on track and prevent problems earlier on as one interviewee stated. The interviewed companies used the technique of brainstorming to get creative ideas from all those involved in the project, whether they were programmers, artists or designers. One project manager said, "We try to get everyone's input because we have a lot of creative people on staff... I am constantly amazed by the ideas that people come up with -- things that I never though of." A project manager must not only be open-minded, but also very efficient and effective. Most projects had a very tight deadline and involved many different people. The manager had the responsibility to keep people on task and ensure the deadlines were met. When asked what would constitute good quality for doing multimedia, a developer said, "the ability to deliver on time and the quality of the work." All interviewees discussed the various stages of testing they used. They were a prototype, an alpha, a beta and a final testing. They emphasized the testing process was not one stage occurring at the end of the development process, but a continuous process occurring at almost all phases [Dick & Carey, 1996; McDaniel & Liu, 1996]. It was a critical phase to ensure the quality of a product and the product would meet the client's needs. Although multiple cycles of formative evaluation were used, the interviewees also mentioned that the summative evaluation seldom occurred. The reasons were often there was a lack of the funding, and the developers had little control over the product when it was delivered to the client.

Hardware and Software

The platform of choice for most multimedia developers was the Macintosh, though one developer used the PC exclusively. Most developers also used PC's to cross-platform their products. Either large or multiple monitors could facilitate ease of development. Macromedia *Director* was the most popular authoring tool cited by the developers interviewed; *Authorware* was also popular, while *Toolbook* was used by the interviewee who developed exclusively on the PC. *Photoshop* was the most commonly used graphics tool. *CorelDraw*, *PaintShop Pro*, *After Effects*, *Adobe Premier*, *Fractal Design Painter*, and *Infini-D* were also used. Programmers were typically expected to know the scripting language in Macromedia *Director* called Lingo, and/or C++.

Tips and Techniques

In the course of the interviews, the developers offered a variety of tips about successful multimedia development. The following included only a sample of the more common suggestions provided by the interviewees.

Planning. Planning is the key to the success of most business endeavors, and this is certainly true in multimedia, where a lack of planning early in the process can be costly in terms of time later. All developers emphasized the importance of planning, and some offered specific suggestions. A videographer explained the need to carefully prepare for post-production while on location: "In the post-production environment, if there is something missing like an ambient audio, you're long past the time you're in production and can just say, 'It would be nice to have this particular shot or this particular audio sound.' In an expensive post-production house, where it would be like two hundred dollars an hour, you have to be extremely prepared or your money is just going down the drain." Some developers pointed out that when a great deal of up-front planning has been done with the client, it is easier to consider changes that the client requests at a later time as change orders, and therefore, the client must pay for the time to make these changes. Some recommended careful planning of the amount of data that would be generated for graphics, text, audio, and video so that the final product does not exceed the 640 MB of memory available on a CD ROM. Another good suggestion made by some interviewees is that it is important to get everybody, project manager, lead instructional designer, art director, video/audio director involved early in the process so as to "avoid pitfalls along the way," because these people what is possible and what is not possible from their perspectives. Finally, early testing on target machines, i.e. the range of machines that are expected to be able to run the final product, will help to guide the choice of media and activities designed for the product.

Time management Skill in managing time in a multimedia environment is based on experience. Two specific suggestions relating to managing the schedule of a project, offered by the interviewees, are: First, in creating the schedule, plan on unexpected problems to arise near the end of the project. "There's a 9 to 10 rule. Supposedly when you have 10% left to do, you really have 90% of it - because that is when all the major stuff happens. So, try to stay ahead of your schedule." A second suggestion is to insert milestones throughout the project. This keeps everyone working toward common goals and deadlines and create a time when people can celebrate their accomplishments throughout the project.

Personnel. Multimedia businesses depend upon the talent of their employees. Therefore, it is important to build a visual, and creative staff. Large businesses may departmentalize, allowing employees to develop talents in one area only, but small companies should look for multi-talented people who can perform a variety of jobs. The staff should constantly seek out and share information about advancement in technologies.

Resources. Effective management of time through careful planning is a key to success. Skill in managing time in a multimedia environment is based on experience. One developer, for example, stressed that experience in post-production as invaluable to ensure all relevant materials are collected during video shooting and avoid wasting time and money for redoing. Another developer cautioned project managers to be realistic about time, and to stay ahead of schedule, because unexpected problems always arise near the end of a project.

Communication with Clients. Because many clients lack a familiarity with multimedia, the importance of educating the client as to the design, capabilities, and costs involved in multimedia development is critical. In case of disagreements with the client on issues of content and design, it is important to remain diplomatic, to attempt to convince the client of the reasons for a differing position, and to abide by the client's final decision. Because clients can occasionally disappear or fail to pay, it is advisable to require the client to pay ahead of time or upon delivery.

The findings of the study provide information on the multimedia development process from a practitioner's perspective. They help to clarify the mystery of what is involved in multimedia production and provide useful tips and techniques from the multimedia professionals. As more jobs focus on the technology of the Information Age, many individuals will be turning toward multimedia as a means of communication, entertainment, and instruction. How can an individual get prepared for the multimedia business? Education is certainly one way to gain entry into multimedia. In addition to taking courses in multimedia offered by universities and colleges, an individual who wants to enter the field should surround themselves with creative stimuli, since multimedia production is a creative, fast-pace, and ever-changing endeavor. A person who wishes to create multimedia products must be prepared, both mentally and physically, for a steep learning curve of the multimedia production process and the software and hardware involved. They should master a state-of-art authoring platform and some of key software used in multimedia development. They should read books and trade magazines frequently in order to understand the theory, the vocabulary, and keep up with the development of the technology. They should be ready to learn constantly as new developments continue to develop in this ever-changing field. More importantly, they should seek opportunities to get involved in the hands-on experiences. An internship or part-time job with a local multimedia company will be very beneficial. Lastly, they should be prepared to sacrifice and spend long hours. Some developers spent over 100 hours per week when working on a project and others spent 40 hours per week. Regardless, multimedia development is an exciting field, as one interviewee put it, "you get paid to have fun."

Computer Mediated Communication in Higher Education: A Dual Perspective

Fraser Lovie
Department of Politics and International Relations, University of Aberdeen, UK
Email: f.lovie@abdn.ac.uk

Abstract: This paper examines some of the potentially problematic areas raised by the provision of Computer Mediated Communication (CMC). The author uses his dual perspective as developer and participant to highlight issues including: the level to which the medium can mask the message; the importance of student motivation and the nature of the group dynamic; the phenomenon of the 'lurking' student; and the role of the tutor-facilitator. These are then placed in context alongside the traditional campus-based teaching paradigm, with the relationship between the increasing use of learning technologies and the nature of traditional campus based teaching also considered. While the issues chosen emphasise some of the potential problems raised by CMC, the author approaches the topic from the standpoint of a CMC convert who firmly believes that the educational experience provided by CMC can be every bit as rich for online students as for their campus based colleagues.

The Impact of CMC

The advent of the information revolution has created a vast new arena of educational opportunities, among the most notable of which is the provision of education at a distance. For that growing section of the educational audience that wishes to study away from the rigidly bounded structures of a campus based degree course, the time and place independent nature of Computer Mediated Communication (CMC) offers a near perfect alternative.

While the nature of CMC varies across a number of alternative forms, ranging from the simplest of electronic mail supported programmes to those which utilise dedicated computer conferencing software, the core element shared by all these options remains constant; the emphasis they place upon the notion of student-centred, open learning. CMC then, in any of its established forms, offers the student an opportunity to take responsibility for their own learning process.

In the 'confusion' of terminologies that has grown up around the educational use of technology, this extension of the notion of truly 'open' learning encompasses all that is positive about the desire to broaden access to education. CMC provides an outlet for a previously disenfranchised section of the learning community and has the interesting ancillary benefit for institutions, under pressure to recruit ever larger cohorts of students, of providing an entirely new 'market' opening for their courses. The opportunity CMC presents in the effort to exploit additional student 'markets' may be one of the central features that defines the ongoing development and implementation of this and other learning technologies.

The asynchronous nature of CMC allows prospective students to consider undertaking a course of study while limiting the disruption caused in other aspects of their lives, most notably familial and employment. This allows individuals to take control of their own learning process, deciding when, where and if to study. This method is by no means new, with correspondence based distance education very much an option for those who cannot study via traditional methods. Yet it is the advent of educational exploitation of technology which has made this type of course both more accessible and more attractive to the 'customers'. With this type of student in mind there are two main markets, existing at opposite ends of the higher education spectrum. Among the most exciting niches for the exploitation of such technology one can consider the potential for extending professional development and post-graduate programmes, both of which cater for groups of students whose motivation to study, it is hoped, would ensure they were pre-disposed to adapt more readily to the rather different rigours of the learning environment provided by CMC. At the other end of the scale are pre-undergraduate programmes enabling those without traditional entry qualifications the opportunity to gain 'access' to University. This too is an area where an alternative method of study may help to make the choice over whether or not to return to education much easier.

While the student-centred, technology-based, distance model of educational provision clearly challenges the traditional paradigm of campus bound education, it is the purpose of this paper to emphasise that while the experience of both staff and students is significantly different, it need not be an inferior experience. Indeed, with careful planning and the required level of commitment on behalf of staff and students, there is nothing to prevent the experience becoming even more rewarding than its traditional counterpart.

The Dual Perspective

In November of 1995, the Distance Education Online Symposium Listserv (DEOS-L) highlighted a forthcoming Workshop to be hosted by Monash-Gippsland University, Australia. The Workshop was designed to benefit those who were either involved in, or looking to move into, the field of, online provision of courses. The rationale behind the venture was to offer interested parties the useful experience of active participation in a conference, thus providing the ideal opportunity to experience the realities of life as a geographically and time challenged learner prior to running an online venture of ones own. Given the benefit of this experience it was hoped that the participants would be fully cognisant of the rigours of that which they would seek to 'inflict' upon others.

For those who participated fully in all aspects of the Workshop, involvement was both enjoyable and informative, with much of the discussion centred on the future direction of CMC and distance education. Unfortunately a relatively high attrition rate was experienced and thus only a hard core of survivors were left to enjoy the full benefits of this activity.

As a developer, the author has become involved in the evaluation of online seminars within the teaching of Politics and International Relations at the University of Aberdeen. As a means of assessing the utility of this method of delivery, a simple electronic mail package (tailored for the purposes of the seminar) was used in conjunction with the World Wide Web (WWW) to provide a basic forum within which a discussion of the topic could be conducted among a volunteer group of students, participating as and when they wished. Briefing materials were housed at a password protected WWW page, and the discussion itself was conducted via a user-friendly, user-configurable electronic mail package (Simeon). A comprehensive package of materials to aid the students' orientation prior to participation was also developed, including guidelines for the number and frequency of their inputs to the discussion, as well as including details of the various deadlines set for rounds of participation. The rationale behind this project was to investigate the potential for such facilities on a broader scale, with a view towards the possible implementation of CMC teaching on a modified or new postgraduate Masters module. This was coloured by the need to remain wary of the cost factor, with the entire venture very much experimental at this early stage.

That said, the seminars conducted via this system were full of thoughtful contributions and suggested to all concerned that this was an avenue worthy of further consideration should a decision be made at a University level that such projects would be recognised for degree accreditation purposes.

The Pitfalls of CMC

The broad trends which had become apparent as a participant in the Monash Workshop, were further corroborated by involvement in this venture and are notably referred to consistently throughout the body of the distance education literature. It is the combination of the author's dual experiences of participation and facilitation in a CMC framework, and the potential hurdles that these helped to highlight, which informs much of this paper. Thus, this paper reinforces the belief that there are several key issues which lie at the heart of CMC development, and remain issues which anyone becoming involved in such an activity will be forced to deal with.

Before going on to examine the issues raised, it is worth emphasising once again that both activities were entirely voluntary. This undoubtedly exacerbated some of the problems encountered, most notably the willingness of various individuals within the respective groups to participate fully given the additional commitments of work, impending assessments and other demands on time. That said, the voluntary basis of such activities could have been a more pervasive element of both activities than was actually the case, with those who demonstrated the motivation to participate gaining much from the activities. In any event, this is an issue that the additional motivation generated by factors such as: the desire to gain a qualification; impending examinations in the subject; and the financial cost of participation, would surely help to ameliorate. All of these factors suggest that when used for the delivery of degree course options, an additional level of motivation would, at least in theory, be guaranteed.

CMC Issues Raised

As suggested above, several issues came to the author's attention, highlighting problems which are commonly encountered in the development and provision of CMC. These included:

Obscuring the Message with the Medium

The first issue which any CMC provider encounters is that the learning environment their students will be expected to learn within is, in general, alien to them. This has two facets: the first is a consequence of the technology itself which can, if incorrectly utilised, cause the students additional problems over and above any they might encounter with the academic aspects of the course and the learning material itself; the second, which is considered later, relates to participation in a course taught via CMC, which may have no face-to-face interaction of any kind (be it either student-student or tutor-student contact). Either or both of these can affect student motivation, feelings of isolation and, if bad enough, may lead to high drop out rates.

While feelings of social isolation may be an unavoidable danger of even the most carefully tailored CMC package, the level of technological proficiency required to participate effectively within the forum should not and as a result is something that can be countered by course developers.

While techno-phobia is something that will gradually become less problematic as the reach of communications technologies gradually pervades all of our working and private lives, there still exists an element (perhaps more so in the UK) for whom the internet and electronic mail remain a mystery. As a consequence, this may undermine their ability to exploit the educational opportunities we seek to make more broadly available via these technologies.

The most logical way to avoid (or minimise the impact of) this, is to keep the medium as user-friendly and as simple as possible. This should then be coupled to a comprehensive set of instructions on how to use and configure the system. This preparation and support prior to participation is documented as crucial to the success of the venture [Hartley et al. 1994] and ensures that students are not left battling their ignorance of technology as well as the course work. Thus whether a simple electronic mail package is used (as in the pilot seminars run in Aberdeen) or a designated conferencing system, a key feature in successful implementation is a concerted effort on behalf of developers to ensure the systems employed do not unnecessarily obfuscate the actual learning interface, with one way of helping to guarantee this being some mechanism via which the students can establish a comfort level with the technology long before being thrown into the discussion arena. Thus a comprehensive introductory package is vital before any activity takes place, perhaps including extensive pre-course activities. With this type of formula in place it should be possible for the students to concentrate on the message of the course material and not the delivery medium [Kaye 1989].

The Creation of a Learning Community

The clear advantage of CMC is the opportunity it provides for people to study independently and at a time and a place which suits them. However, the fear of social isolation, as identified above, is an ever present feature of CMC and other distance learning technologies [Ehrmann 1995]. It has been asserted previously [Kaye 1992] that these social shortcomings may even outstrip technical factors as barriers to the success of the class, with students encountering an educational experience for which they find themselves entirely unaccustomed. If students develop an attitude that they are isolated from the group it may only be a short step from there before the student is tempted to drop out of the course. Thus there is a fear that the inherently alien nature of the group dynamic will lead students to re-evaluate their involvement in the course.

While good facilitation and an easy to follow medium can help alleviate these problems, the primary responsibility here would appear to lie in the hands of the participants. Having opted for the independence of CMC study, it is hoped that the potential shortcomings of the medium will have figured in the students' assessment of whether or not to study by this method. That the more mature learner may adapt more readily to the collaborative learning style that CMC demands [Hansen and Gladfelter 1995; Gould et al. 1995], suggests its audience is limited, with an emphasis placed upon those for whom the tools required to learn in a student-centred environment (where the dominant actor is not the tutor or lecturer but the students themselves) is not a negative feature. There is certainly no reason to suggest that if the participants take their dual responsibilities (to themselves and to the group) seriously that the more thoughtful and reflective responses possible in a CMC environment should not produce a viable and inclusive community spirit [Newman 1990].

Unfortunately it may be an inevitable side effect of CMC that it will produce a residue of such problems and as a consequence the possibility of higher drop-out rates is something that will have to be factored in to the use of CMC as a delivery option. However, as mentioned above, the gradual spread of such technologies should ensure that people become ever more willing to accept the potential dislocation that may come as a result of electronic communications. As tele-working becomes more common and electronic media command an ever increasing percentage of all information exchanges, CMC as a forum for learning will appear less alien.

The Phenomenon of the 'Non-Active' Participant

This oxymoron is used to describe the CMC equivalent of the face-to-face tutorial student who turns up to classes, sits at the back and patently fails to become involved beyond the merely passive act of listening. These non-active participants, affectionately termed 'lurkers', are also a notable part of CMC based courses [Gould et al. 1995]. However, there is a major difference between the two: whereas participation in a tutorial is but one facet of the learning experience of a campus based student - part of an integrated package including lectures and ready access to tutors, this is altogether different from CMC students, for whom their only chance to actively engage in discourse about their subject comes within the computer discussion or via other impersonal communications such as by fax or telephone. Thus the phenomenon of lurking is an altogether more destructive element when found in such activities, with such failure to participate a clear danger to the cohesion of a group which depends to a much greater extent on the active participation of all those involved. With this sense of community partially dependent on the equitable participation of all those involved, an unwillingness on behalf of some members of the group to fulfil their responsibilities could seriously damage both their own and their colleagues learning experience.

This is especially relevant because CMC is widely accepted to break down the traditional barriers which exist to student participation in discussion [Saiedian 1993], such as: shyness, a lack of time to compose their thoughts, insecurity regarding the line of argument they wish to pursue and so on. That these barriers have no apparent place in CMC, only help to make this phenomenon even more galling for tutors and other participants.

There are several possible ways around the lurking phenomenon. Among the most obvious of these may be the decision to grade submissions, thereby forcing students to participate if they are to successfully complete the course. The need to have external verification of such grades is attainable via the archiving of submissions which most forms of CMC can provide. An alternative could be the use of 'learning contracts', where students agree to fulfil their responsibilities to the rest of the group, including full participation as and when required. Within a voluntary cohort such enticements or threats are largely irrelevant, although of those who volunteered for the Aberdeen seminar, all submitted at least one thoughtful response and several responded on multiple occasions. Whichever method is used, the necessity for active participation in CMC demands that such passive involvement be minimised through some mechanism.

The Role of the Facilitator

Many staff members fear the introduction of new teaching technologies. This is often based on an ignorance of the technology itself or, perhaps more often, a fear that the students' education will suffer as a consequence of the lack of direct contact. The former can be countered through staff development and training, although there may be an hostility towards the technology being employed and a subsequent lack of recognition for the necessity to train staff in these methods [Bates 1990]. The latter may only be dispelled as the use of such technology becomes more widespread and involvement proves there is no qualitative difference between CMC and traditional teaching [Hartley et al. 1994].

The undeniable truth regarding the use of CMC is that the role of staff involved in the provision of such options will and must be different from that which they play in a face-to-face environment. The facilitation of any online activity is a far different creature than tutoring in a traditional seminar environment [Davie 1989].

The level to which academics adapt to this alternative environment depends on the individual [Hansen and Gladfelter 1995] and their propensity to adapt their teaching style. While it was suggested above that technical requirements be rigidly set down to minimise differences, this inflexibility in the technology is the antithesis of the approach which should be adopted by a CMC facilitator, where in most cases maximum effectiveness will be achieved through a minimalist involvement, encouraging and prompting but not orchestrating. The facilitator's role is to develop the environment within which the student body can learn actively and interactively.

The 'learning community' identified above, is achievable as long as the students are engaged in a programme which encourages them to discuss the topic multi-laterally and as a group to tackle their problems and discuss the relevant issues. This is a new approach for those whose didactic background is more suited to the passive learning experienced in the more traditional delivery methods of conventional lectures and tutorials. While some may be reluctant to accept this, active learning is something that is increasingly identified as 'a critical variable in learning and cognitive development' [Harasim 1990]. Indeed, the notion of student-centred learning is something which would be beneficial if applied more broadly in traditional course delivery.

Conclusions

CMC would appear to be the ideal medium for truly 'open' distance learning. It provides a forum for the discussion of any issue which you care to study and if combined with other technologies, such as the World Wide Web and CD ROM can ensure that a remarkably broad learning experience is made available to students in their own homes. There is certainly no reason to suggest that the exposure to relevant information, meaningful discussion of the issues involved and academic support need be any less impressive than that which a traditional campus bound student experiences.

The issues highlighted in this paper can become problematic if left unaddressed, although they can just as easily be countered by a variety of means, including: thoughtful course design and structure; selective targeting of a student cohort willing to adapt to the environment; and perhaps most important of all, as a result of a programme of staff development designed to instil in the tutor the attitude required to perform well in an entirely novel teaching mode. While this latter may be one of the more difficult solutions to achieve, with distance education still considered by many a second class citizen. Luckily those who have become involved thus far tend to be those receptive to more progressive teaching methods. However, when this mode of delivery becomes more widespread (as would appear to be inevitable) some serious thought will have to be devoted to a re-skilling of tutors more used to traditional educational methods.

Perhaps inevitably CMC is forced to justify its existence and as a relatively new educational medium it is open to certain criticisms. However, the novelty of the medium does not necessarily make it inferior to traditional teaching methods and for many it can make all the difference between having the opportunity to study or not.

All innovative learning technologies are forced to satisfy existing pedagogic models and prove themselves capable of guaranteeing the quality of education which it is believed campus based teaching can provide. Yet to many involved in CMC, the very fact that they are under such pressure to ensure the pedagogic worth of their medium has ensured that their courses are better designed and more adept at forcing the students to learn actively than many traditionally delivered alternatives. The irony of the situation is that the thought and preparation required to produce effective CMC would surely be a benefit in many campus based courses.

Abstract: Phase I of the Acadia Advantage program in 1996, put IBM notebook computers in the hands of 375 first year students and 43 Faculty members to use in computer and technology-enhanced courses. An Academic Development Centre was created to assist faculty with the effective use of technology in and out of the classroom. The centre provides training sessions, brings in guest speakers and provides computer based solutions to academic needs. The Automated Courseware Management Environment (ACME) is a modular system that was developed to provide faculty with a way to create comprehensive web-based course pages without any knowledge of HyperText Markup Language (HTML). The ACME modules include a testing module (OTIS), a discussion group module, an upload-notes module and a course evaluation module.

Introduction

In September 1996, Acadia University began Phase I of the Acadia Advantage program. The program brought 375 first year students and 43 Faculty members to use IBM notebook computers in computer and technology-enhanced courses. Eight classrooms, ranging in size from 30 to 105 seats, were redesigned to include full multimedia teaching consoles for the instructor, and network and power connections at each student desk. The campus was completely rewired bringing fiber-optic cable to each building, and a high-speed network was put in place. All student residence rooms were wired for data, phone, and cable, and over 400 network hookups were installed throughout the Library, Support Center, and student common areas.

During the 1996-1997 academic year, the notebook computers were used as an integral part of first-year courses in Business Administration and Computer Science, along with selected courses in the Arts, and Sciences. In total there were 47 Acadia Advantage courses offered.

In September 1997, Phase II of the program will begin, and all first year students will be issued notebook computers. By the year 2000 all Acadia students will be a part of the program. All courses on campus will be able to make use of commercially available and Acadia developed software as well as the Internet and the Acadia Intranet. Students will use the notebook computers as tools with which to participate in class exercises, record and download notes, take online tests, and participate in out-of-class discussion groups, writing assignments, and online tutorial sessions.

The Sandbox

In May 1996, the Academic Development Centre, which became known as "the Sandbox", was created and given the mandate to assist Faculty with the effective use of technology in and out of the classroom. Three full-time consultants, along with 14 summer students, were hired to assist with courseware development, evaluate existing material, provide workshops and seminars, and work one-on-one with the 43 faculty in the Phase I program. During the 1996-1997 academic year, two of the full-time consultants and 8 of the part-time student staff remained to continue providing support, and to begin training of the 125 Phase II Faculty who received their notebook computers during September and October of 1996. Training sessions cover everything from the basics of Win95 to advanced CGI programming.

Courseware

It was clear from the inception of the Sandbox that the best way to make courseware material available to the students, both on and off campus, was to use the World Wide Web. After careful evaluation of several existing products which allowed schools to develop their course material for the WWW, it was clear that Acadia required a system with more flexibility, greater ease of use, and lower overhead in terms of ongoing support and management than was currently available.

The Automated Courseware Management Environment (ACME) was developed to meet the need amongst faculty and staff for a simple, intuitive, and efficient method of getting course information on the WWW, with the time constraint of bringing 47 courses online in a matter of a few months.

ACME is a modular system, which through the use of forms and cgi scripting allows faculty to create comprehensive web-based course pages without any knowledge of HyperText Markup Language (HTML). The primary aim of ACME was intended to be a tool for generating Course Homepages, however it also has several optional built-in modules such as an online testing system (OTIS), an online discussion group system (ODGS), a secure course-evaluation component and an uploading course notes option. Several other modules are in development. The remaining part of this paper will briefly discuss how ACME and its components work.

ACME

ACME is a collection of scripts, written in Perl, that provide a web-based environment designed to facilitate the presentation of course information. Faculty and students are identified through an authentication check, and are given varying privileges in the system depending upon their identity. After requesting that their courses be recognized by ACME, individual professors are provided with a personal profile that grants them course editing privileges. Utilizing a series of form templates the professors can then create and edit any number of aspects of their course, which are created as web pages "on the fly" by the scripts when a student comes into the course.

Although ACME is primarily designed to facilitate the creation and maintenance of these information-containing web pages, it has been extended, through modules also written in Perl, to provide extra functionality.

Making it work

Before they are able to view web pages created by ACME, users are first required to type in a name and password (which can be changed after the first login), and pass an authentication system supported directly by the web server itself. ACME's home page is stored in a directory with access controlled by this authentication system. It should be noted that ACME takes advantage of Perl's encryption capabilities to encode user's passwords so no plain-text passwords are ever visible.

Every user in ACME has what we refer to as a profile. Each profile is a text file that contains the user's full name, e-mail address, and login name. In addition, the profiles also contain an entry of all the courses that the user is registered in or has access to. This information is obtained through Acadia's Registrar. For faculty, there is an extra entry indicating that they have 'Instructor' access to the courses they teach, which allows them editing privileges.

Once a student user has entered the system, they can either go to a dynamically-generated list of all courses registered in ACME listed by year and discipline (Figure 1), or go to their profile page (Figure 2) generated by a cgi which lists all the courses in which they are enrolled.

The core functionality of ACME is the course editing area. From here, a professor can customize what information is available to the students and how the course is displayed. There are several 'themes' available such as Professor Information, Schedules, Related Texts, Teaching Assistants, and Curriculum which can be filled-in by the instructor and made available to their students. We have also designed a set of templates that allow a choice of colour/texture schemes, header/footer styles and layouts. Most importantly these templates (ie. the page layout) can be changed without having to re-enter the course information, and new design templates can be added at any time allowing a custom design that fits the instructors' taste.

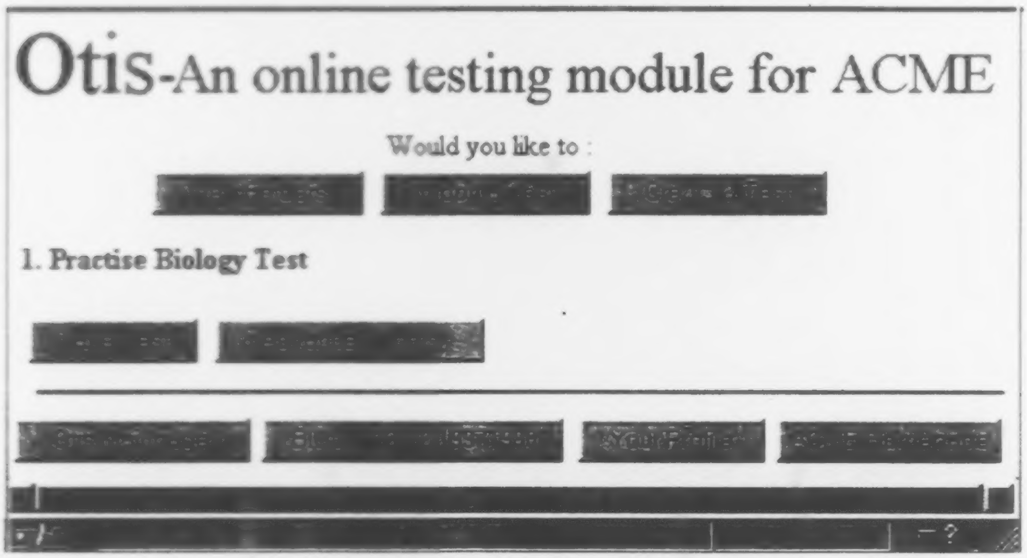
Module Plug-ins

Modules extend the functionality of ACME by building on and taking advantage of the system architecture that is already in place. Modules need only know which user and course is making use of them to be able to function properly. As they are an extension of ACME, this information is immediately available, making for a seamless integration of ACME and the modules. Currently there are four modules in place with several more planned. All are optional additions to the system, and the instructor controls the use of any one or all modules in a course.

Testing Module (OTIS)

The OTIS module provides online testing capabilities for any course in ACME. Instructors can create tests (Figure 3) using a series of templates that have enough flexibility to allow formatted text, images and, in the case of French tests, accents. The instructor can also perform advanced operations on the tests including editing, viewing student results, purging the results, moving the test to an archive, or making the test available to other courses.



Otis-An online testing module for ACME

Would you like to :

1. Practise Biology Test

Figure 3: Instructor view of the OTIS home page.

Tests are created in a three-step process. The first step is to tell the system the number of sections, after which the system presents the user with a set of options for each section. In the second step, the instructor would specify the number of questions that will appear in each section, and what type of questions each section will contain. Otis currently supports "fill in the blank", "multiple-choice", and "essay" questions. The final step of the test-creation is to actually enter the test data into a template created by the information input during the first two steps.

Templates have been designed to allow section titles, questions, multiple answers, and comments to be entered by the instructor. Questions can also be randomly displayed to the student from a larger set of entered questions. If the randomizing function is chosen, the instructor can input the number of questions to be displayed. All of this information is then stored in unique data files allowing the instructor to edit the test at a later date, simply by accessing the 'Edit Test' option.

Once the test is ready to be made available to students, it can be moved into one of the available archives in the course and viewable by the students. Students can then after proper authentication, call up the tests at their leisure, input their answers, and submit them for marking. With the exception of opinion questions, all of the

BEST COPY AVAILABLE

questions will be automatically graded and the results displayed to the student utilizing frames and Javscript. At the discretion of the instructor the correct answers may also be displayed. If there have been comments entered corresponding to the answers that have been submitted, they will be displayed also. Also at the discretion of the instructor any previous tests may be made available to the students.

A record of the test submission is stored in a result file that the instructor can view at any time, and purge when necessary.

Discussion group module

This module was created to enable on-line threaded discussion groups for each course within the ACME system. Once a student enters the system, he or she can go to any course in which they are registered and enter one of that course's discussion groups. Within that group they can participate in any number of subtopics created by the Instructor. A student can both view and enter comments about the topic or post a reply to a comment that another student has written (a threaded response). Each discussion group provides the option of privately e-mailing the person that posted any message by clicking on their name, or to follow up directly in the public discussion area.

Rather than displaying a list of names and subject lines as in a standard newsgroup, the discussion group pages display the full text of all comments. The instructor of the course is given the ability to add and remove discussion groups and topics from the course, change group and topic information after creation, and remove entries from topics. Before any change is made to a discussion group the program first checks the user's profile to ensure that that they have been granted the rights to modify the group in question. If the user isn't properly authenticated or authorized, he or she will receive a warning message, and the administrator is notified of the action.

The system provides an easy-to-use graphical environment to facilitate collaborative learning. Some professors have organized their students into "teams" by providing groups on their system such as "Group One", "Group Two" etc. and having each group make comments only within a specific discussion.

Upload Notes

The Upload Notes module gives the instructor the file-by-file, directory-by-directory control they require for organizing files which they want to make available to their students. The file upload feature (a new feature of HTML) is used to query the instructor for the file they wish to make available. This file can be anywhere the instructor can access including their local hard drive, directories on their Intranet or the Internet. Once selected, the file is transferred to the Upload Notes system, which checks to see that the Instructor is not exceeding their space allocation, or that the type of the file uploaded is inappropriate. Most file types can be uploaded; however, inappropriate files can include a content type that is unknown to the server, or a cgi file that must be rejected for obvious security reasons.

The main view of Upload Notes shows a fully expanded directory tree with all files displayed as links. Students simply click on the file they wish to view.

Course evaluation module

This module is part of the ACME system but it is not within the control of the course instructors. The module appears in each student's user profile late in the term and becomes activated during the evaluation period. Once a user enters the evaluation system they are presented with the courses they can evaluate (if any). The student answers each question by selecting the appropriate response and entering any written comments at the bottom of the page. The results of each of the course evaluations are stored in three databases: one of which stores all of the textual information, another which stores the values for all of the courses evaluated, and the last storing the average "score" for each question. Additionally, as a course can only be evaluated once by each student, a database stores a list of the users and the courses they have evaluated. This information is used to insure a student does not evaluate a course twice.

At the end of the evaluation period the resulting databases are turned over to a designated individual that has sole access to the information. They have the ability to view and download the results, which then can be imported into any spreadsheet program.

Conclusion

When ACME was first presented to faculty, staff, and administration, response was wholeheartedly positive, and it has continued to be positive throughout the development of the system. For Acadia one of the greatest strengths of the ACME system is that it is a homegrown package. Over the past several months ACME has grown and improved through continuous evaluation by the programmers, and from the generous comments and suggestions made by Acadia faculty. The future of ACME has few limitations and it will continue to develop as a simple, convenient online environment for both Acadia students and faculty as new ideas and requirements come to the attention of the ACME development team.

An Environment for Multimedia Communication Literacy

Abstract: The goal of this study is to characterise an environment for *multimedia communication literacy* (*MCL*), which is the next generation of the computer and network literacy. Starting with the definition of the *MCL*, we describe its importance of the experience of real-time multimedia communication. What is a suitable environment for the *MCL*? To investigate it, we made several experiments of distance learning by using ordinal lectures. In our experiments, we used a high-speed ATM (Asynchronous Transfer Mode) network with the Internet collaboration (video, audio and whiteboard combined), called the Mbone (Multicast Backbone) tools. We present measurements on the network traffic and the results of the questionnaires on distance learning to know its effectiveness. From these results, we discuss on the bandwidth required for distance learning and the requirements of the presentation tools. In conclusion, we suggest that the *MCL* is required in the future.

1 Introduction

High speed networking has introduced opportunities for new multimedia communication as video conferencing and VOD (video on demand) which will most likely use multicasting to transfer data across networks to several recipients. The first such applications have come into wide-spread use on the Internet, using the Mbone (Multicast Backbone), a virtual experiment network [Macedonia & Brutsm 94]. An example of the experiment is shown as [Banerjea et al. 94].

On the other hand, using the Internet presents some unique opportunities in the education because teaching/learning by the Internet is different from the traditional lectures or classrooms. It is one of the accelerators of computer and network literacy education. From the network technology as the above, the educational use changes in a multimedia communication environment. For example there is an approach like asynchronous or on-demand education [Harris & DiPaolo 96]. The other is interactive distance learning [Lee & Sullivan 96] [Sasse et al. 94].

Based on the background as the above, the different literacy education from the conventional one is required in real-time multimedia communication using high-speed networks. Computer and network literacy currently considered is not enough for it. The goal of this paper is to suggest the required literacy education and to investigate an effective environment for it.

First, we define *Multimedia Communication Literacy* (*MCL*) and describe its necessity and importance in Section 2. To consider an environment for *MCL*, in Section 3, we present the experimental environment

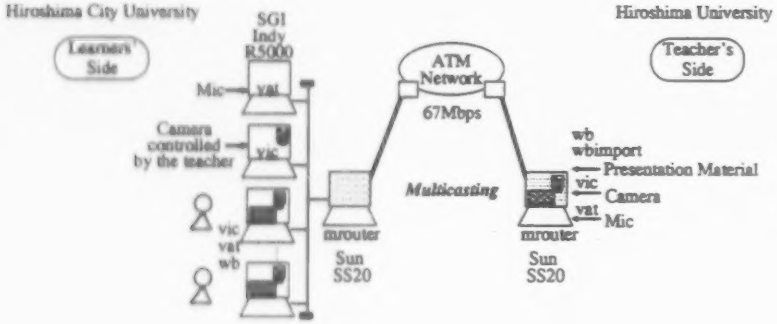

Figure 1: System Configuration (The Second Experiment)

using high-speed ATM network and the Internet collaboration (audio, video, and whiteboard combined) called the Mbone tools for distance learning. We present some measurements on the network traffic and the results of the questionnaires to the learners on effectiveness of the distance learning. As the results, we summarize an environment for distance learning. Finally, we conclude on the importance of the *MCL* and its effective environment and describe the future problems in the last section.

2 Multimedia Communication Literacy

Computer literacy is used as the concept to learn how to use computers and network literacy is to learn how to use the network services based on the Internet like E-mail and to search the suitable information through networks. Here we define the *Multimedia Communication Literacy* (*MCL*) as the literacy to operate interactive collaboration tools of video, audio and related things on the Internet for real-time multimedia communication. As new literacy using the Internet was naturally required by its emerging, the definition of *MCL* is natural in the next generation of computer and network literacy using high-speed networks and real-time multimedia communication. The *MCL* needs different factors from current network literacy because it requires interactive and real-time operations on a computer using the Internet.

Though interactive tools on the Internet are being developed, there is rare opportunities for students to use them. The *MCL* is significant to gain their experience in using them as usual communication methods not only for the distance learning but also for various occaisions in daily life. An environment using high-speed networks and multimedia communication is needed to learn the *MCL*. We discuss the effective environment in the next section.

3 Experiment Environment for Distance Learning

3.1 Outline of Experiments

The purpose of our experiments is to summary what network environment is needed, what kinds of tools are easy to use for teachers and learners for distance learning and to consider how effective this environment is for the *MCL*. The network between two sides of the teacher and the learners in the experiments is by the ATM backbone. The bandwidth, 67Mbps is available for this experiment. The system configuration in the third of our experiment is shown the [Fig. 1] for the example. We use the Internet collaboration tools (audio, video and whiteboard combined) and the mechanism of remote camera control. The following is the details of them.

Figure 2: The example of the screen dump image of the lecture

- Video: *vic* (Video Conference) [McCanne & Jacobson 95]
- Audio: *vat* (Visual Audio Tool) [Jacobson & McCanne 95]
- Presentation Tool: *wb* (White Board), *wbimport* [Jacobson & McCanne 93]

  Presentation pages of course material are displayed on a *wb* window. Before a lecture, all pages are cached into a raster memory by *wbimport*. A teacher can turn its pages, move a pointer on the page and write characters and figures for additional explanation in real-time. Also, *wb* can be used a shared board to write by both sides of the teacher and learners at the same time.
- Remote Camera Control: *Netscape + the UNIX scripts*

  A teacher can see moving pictures of any location of the learners' room by clicking the buttons on the special viewer of the Netscape with the embedded cgi-bin function using the UNIX scripts. He can control the remote camera to any direction (right/left and up/down) and zoom operation.

A teacher operates these tools on his own workstation (in short, WS) himself. The situation of learners side are different in three experiments as the following.

1st) There is only one WS for the collaboration tools in the learners' side. It receives data of moving pictures and voices from the teacher side through networks. Each learner can see the same images as that WS monitor on his individual monitor (19 inch) by a image transfer system. This system is the special equipment with functions to transfer video images of one specific WS to all other monitors in the same resolution as the specific one.

2nd) The number of WSs for the collaboration tools is the number of the learners. Different form other two experiments, each learner can operate all tools on his own WS with its camera and microphone himself. It is by multicasting.

3rd) There is only one WS to use the collaboration tools in the learners' side and learners see a wall screen (over 200 inch) projected of the monitor of that WS. The difference from the previous two cases is a shared big screen by all learners. We used a VICTOR ILA-M320S video projector (over 1000 TV lines and 2300 lumen) to project WS video images clearly.

BEST COPY AVAILABLE

The detail of the experiment environment is shown in the [Tab. 1], and the [Fig. 2] shows the example of screen dump image in the teacher side. Learners see the similar windows on their own monitor or a big screen during a lecture.

	First	Second	Third

		Sun SS20 (75MHz, 96MB) Solaris2.5	

Table 1: The Detail of Experiment Environment

3.2 Results

In the environment as the above, the maximum bandwidth during the lecture is 600 Kbps from the [Fig. 3]. The learners' impression on images (both moving pictures and presentation pages) and voices is that there was no problem for an ordinal lecture from the result of the questionnaires as the [Fig. 4], of which the total number of answers is 123 through three times. The question items 4 and 14 in the third were omitted because the learners are the same in the second. The vertical axis of the [Fig. 4] means normalized average of each questionnaire item. To obtain each average, answer items of a question are weighted from 1 to the number of its answer items. Higher value of an answer item means the better result of the experiment environment for distance learning.

3.3 Discussion

Though emphasis of a high-speed network is the current tendency for distance learning, the bandwidth, 600 Kbps, gives the same quality of ordinal lectures in the case that course material can be prepared in on-line presentation style like our experiments in advance. The importance is ensured bandwidth about 600Kbps for distance learning.

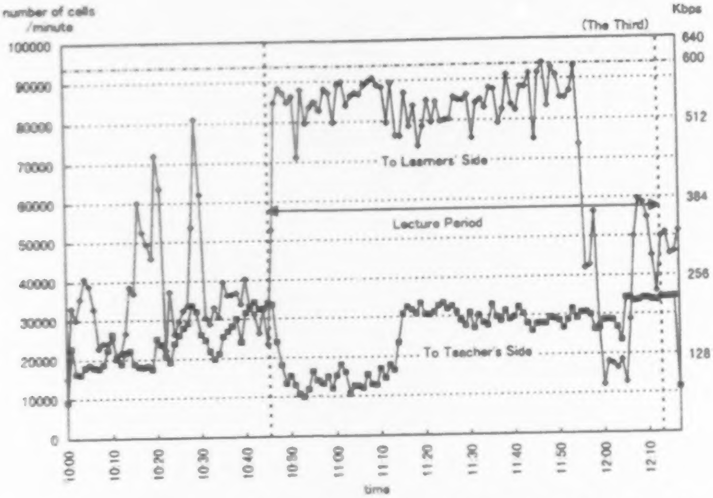

Figure 3: The number of Cells of Transferred Data (The Third Experiment)

Also the result is obtained that distance learning itself was very attractive and effective for the learners. This style of distance learning is effective for reinforcing attentions and understanding of subjects on the network, computers and related things from their free descriptions in the questionnaires, even though they did not operate the tools themselves positively.

Focus on the difference of styles on displaying images and hearing voices, that is, the difference between an individual monitor with a speaker and a microphone and a shared big screen with a speaker and a shared microphone. there is no obvious tendency preferring one of two styles from the questionnaire results. In either case, the brightness and clearness are enough through these experiments. It is important for distance learning to care these points. In spite of the audio and visual styles, a on-line presentation tool is the key point for distance learning. Its necessities are to display course material clearly and the pointing and writing functions by both sides of the teacher and learners. *Wb* is the effective tool displaying PostScript images. We obtained its effectiveness from the learners as [Fig. 4]. However, it is hard to display synchronously with turning pages because of the over load to process the PostScript images. The cache in a raster memory is needed before a lecture. So we should improve functions such as capture of raster images, dynamic capture of any other windows and input method of various language code.

4 Conclusion

Concluding this paper, we first suggest that the *MCL* is required as the next literacy for high-speed networks and the real-time multimedia communication in the future. Next, we show the concrete environment for the *MCL* by the experiments of distance learning to investigate a good environment for the *MCL*.

If the *MCL* is usual as literacy education, it will be natural and easy for the people living in the next generation of a cyberspace to use multimedia communication method in the future. As future works, we should consider the training of teachers for the *MCL*.

Abstract: This work suggests WWW server of a special architecture which improves customization of educational material delivered over the Internet to end user. Here we also describe so-called Distributed Learning Environment. Server that we suggest deals with so-called Virtual Multimedia Documents (VMD) dinamically in order to avoid difficulties while dealing with HTML documents, because HTML uses different tags for different types of media objects. Structuring of hypermedia database and its elements is also described in this article.

1. Introduction

Generally, World Wide Web (WWW) rests on three fundamental concepts:

- HTTP (HyperText Transferee Protocol);
- the URL (Uniform Resource Locator) addressing/naming scheme;
- HTML (HyperText Mark Up Language).

HTML serves as the de facto standard for structuring, storing and exchanging WWW documents. HTML provides a solid background permitting different vendors to develop a variety of browsers running on different hardware and software platforms, but displaying data in approximately the same way [Nielsen 1990].

Originally, HTML aims to provides two primary capabilities: - so-called Mark Up facilities for describing how textual information should be represented or displayed. - a mechanism for including within a document links or references to other documents; thus, when a user "selects" a link, the document associated with that link is accessed.

However, the consistency provided by HTML comes at a cost: it is currently very limited in its data formatting [Nielsen 1990], multimedia and interactive capabilities, far more so than what most users need to create a modern educational applications (i.e. courseware).

All recent HTML developments can be seen as attempts to overcome the above mentioned problems, currently, HTML allows a document to include other forms of media objects, such as external files interpreted by so-called Helper application or by Plug-In applications, Java applets, Java scripts etc.

Unfortunately, these recent enhancements of the WWW concepts contradict to a basic idea of platform independence which made HTML the de facto standard. In other words, HTML documents are loosing compatibility due to embedding different media. Thus, a Java capable browser is needed to view Java applets or scripts, special Helper applications should be installed to provide access to interactive courseware modules, etc.

It is widely recognized now that a special customization mechanism is needed to disseminate courseware materials to a big number of users having different software and hardware installations.
In this context, we develop a so-called Distributed Learning Environment which is a WWW server providing, among other capabilities, a dynamic customization of educational materials to a particular user profile [Maurer et al. 1994].

2. Architecture of the Distributed Learning Environment

The system operates with so-called *Virtual Multimedia Documents* (VMD) [Maurer et al. 1995]. A VMD is a semantic unit integrating a number of media objects such as text, picture, sound, video, animation, or simulation. Actually, any types of media objects can be combined into a VMD.

Each multimedia document has an actual contents and a logical structure. Both are defined by the author of a document and are represented in a special data structure kept on a server site. The data structure is described in more detail in the next section.

Informally speaking, VMD is a number of so-called clusters which are interrelated much in the same way as alternative media objects might be embedded into an HTML document. In a simplest case, a VMD can consist of a textual document with an embedded cluster. Each cluster contain a number of alternative media objects one of which is dynamically selected when the VMD is presented to a client [Maurer et al. 1994].

Thus, we can say that when a VMD is presented to a client, a context of use is superimposed on its contents and structure to affect the presentation. This effect is produced dynamically by the server by means of presentation mappings and depends on the chosen navigation path, user profile, or technical circumstances.

For instance, a particular document or individual media object may participate in different hyperlink structures and, hence, be displayed using different sets of anchors, i.e., active elements which provide a possibility to jump to other media objects.

It may also be the case that the same contents must be presented in different languages or that a certain media type must be mapped into another type because the former cannot be visualized by a particular hardware/software installation (e.g. animation to a still image) or perceived by a particular user (e.g. text to speech, large print, or Braille mappings supporting visually impaired users).

Depending on the desired type of re-use of a document it may also become necessary to present copyright information on different levels of granularity. Server generates resultant document presentations for clients using the following information:

- logical structure showing the contexts in which a document participates (for instance, a document, which is stored once on a server, may be visualized differently when being re-used within two different CAI courses);
- user profile capturing special parameters defined by a user, such as language, software and hardware preferences or media type preferences (e.g. if the user is disabled, the type of some media objects should be replaced with another type);
- client and connection profile determined by technical parameters at the client site or communication related parameters such as help-applications and plug-ins availability, Java applets capability, transmission speed, quality of service or quality of delivery resulting, e.g., in variation of image

resolution, presentation size, color depth or replacement of continuous video sequences by still images.

3. Structuring a Hypermedia Database

An essential property of hypermedia is a non-linear chaining of different types of multimedia documents. More precisely, hypermedia deal with data structures imposed on a top of a collection of multimedia documents. Thus, hypermedia can be maintained in a special type of databases. A hypermedia database is not simply a bucket full of multimedia documents but is structured and also large in terms of number of components and storage size.

The data model we propose, supports the following structuring elements:

- collection
- cluster
- virtual multimedia document.

Collections can be built from other collections or from virtual multimedia documents. Collections are associated with particular navigational mechanisms explained below.

Clusters represent families of media objects of related contents. They allow an author to combine alternative representations of a particular piece of information, e.g., a piece of text in different languages, their spoken versions, and a screen-reader compatible version. Upon client access one document out of a cluster is selected by the server depending on context information as discussed earlier. Media Objects are the smallest units of contents representation. They are further combined into clusters and virtual multimedia documents. The following points relate these terms to the role and functionality of the hypermedia database.

Virtual multimedia documents are stored in a special internal format. Each multimedia documents has its unique logical structure which is defined as references to embedded clusters (see Fig. 1).

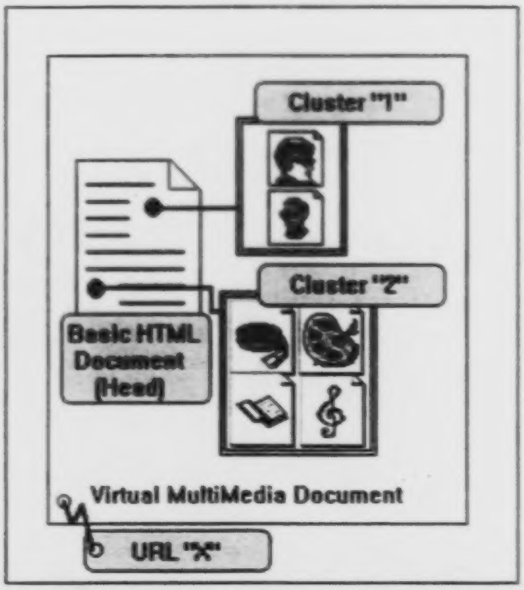

Fig. 1: Internal Structure of a Virtual Multimedia Document

This structure is determined by the author of a document and cannot be altered by a server. Clusters can be seen as containers for alternative media objects which can be added/modified independently. Thus,

BEST COPY AVAILABLE

the virtual multimedia document is a template which is filled with actual content (i.e. with media objects) in due course.

When a media object is stored into a hypermedia database, it is inserted into one or more clusters and is provided with a number of attributes which are determined by the author. Thus, a number of related media objects is combined into a cluster to provide a possibility for the server to automatically select one member of such cluster to serve the special profile of a particular user. For example, a document written in a particular language is automatically selected relying the client's language preference. Similarly, a special viewer for visually disabled users may always set the user preference causing the server to select a speech or text fragment instead of any other media.

When a virtual MM document is stored into a hypermedia database, it is included into one or more collections. Collections impose an additional navigational structure on multimedia documents participating in a collection. For example, a collection can be scanned in a forward or a backward direction or a member can be selected through a pop-up menu [Maurer and Scherbakov 1996].

4. Authoring and Visualisation of Virtual Multimedia Documents

Virtual multimedia documents are authored much in the same way as ordinary HTML documents. The only difference is that all references are made as special non-HTML tags. The tags refer to clusters in an unified way. The term 'in an unified' way is very important in this context since the HTML supports different tags to embed different media objects including a necessity to provide some very technical details on such embedded files (say, position of an applet, size of a window to be used, etc.). In our case, authors simply refer to a cluster by its unique name.

A typical example would be a virtual multimedia document having a reference to a cluster 'Figure X' tagged as:

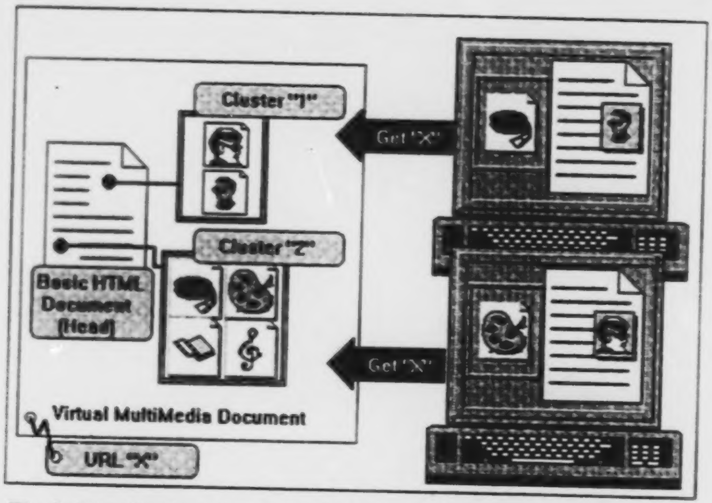
<! Refer Cluster 'Figure X'> See Fig. X</Refer>

Note that only one of such cluster members is dynamically selected when the VMD is presented to a client. The system uses special information on a particular user (a so-called user's profile) and selects a media object which is most suitable for visualisation on the particular WWW client (see Fig.2).

The cluster 'Figure X' may contain a still image 'FigX.gif', Java Applet 'FigX.class', an external file 'FigX.hmw' and some other media objects as members.

When the document is presented to a client, the non-HTML tag is dynamically replaced by one of the following HTML tags:

- <IMG SRC="FigX.gif"> if the client is not Java capable and does not have a Helper-application or Plug-In to deal with '.hmw' files
- <EMBED SRC="FigX.hmw" WIDTH=80 HEIGHT=60> if the client has a Plug-In to deal with '.hmw' files
- <A HREF="FigX.hmw"> if the client has a Helper application to deal with '.hmw' files
- <APPLET CODEBASE="..." code=FigX.class WIDTH=80 HEIGHT=60> if the client is Java capable and does not have a Helper-application or Plug-In to deal with '.hmw' files



Cluster "1"

executed in the prescribed order when the pag fun characteristics of its list of objects the page is displayed (See Fig 1).

A page can be quite complex and powerful unit in itself, with some highly sophisticated behaviour (See Fig 2).

HM-Card Editor offers comfortable, high-level authoring of pages without a scripting language, but uses a visual programming approach to define interaction and flow of control in applications (See Fig 3).

Defining an object for use in a page involves choosing a type of the object, setting the required or optional parameters, and possibly determining the object's position on the screen.

5. Conclusion

As can be seen, the new media capabilities which are currently introduced into WWW technology are not so useful as they could be. In general case, embedding such advanced media objects into HTML documents makes them dependent on a particular hardware and software platform. We believe that a special customization mechanism would eliminate the problems caused by the fact that HTML documents have 'media specific' tags embedded in them. This customization mechanism could be accomplished by dynamic mapping the rich structure of so-called virtual multimedia documents onto the simple HTML tags using a particular user's profile to select media objects for presentation.

A number of courseware examples built upon the described principles are available from: *http://www.iicm.edu/courseware*

Jodrey School of Computer-Science, Acadia University, Wolfville, N.S. B0P 1X0, Canada; email: solid@acadiau.ca

Abstract: Computer based teaching (CBT) presentations are large and complex software systems that need extensive and thorough documentation in order to make their development and maintenance possible. There are many well-known methods used to document programming systems. A CBT, however, is unique in that its environment is typically distributed, and consists of many properties and objects that are stored all over the application. Therefore, it requires a different method of documentation that has specific features to keep track of the system's development.

This paper describes the design and implementation of ***"XDoc"***; a documentation system for ToolBook's authoring environment. XDoc supports interactive access to both the ToolBook application and its documentation. It can be used either to create documentation on-line, or off-line (that is for existing applications). Xdoc also solves the typical problem of inconsistency between an application and its documentation by using hypertext links.

1. Introduction

Documentation plays a major role in the task of developing and maintaining software systems and Software Engineering provides various methods to help create documentation, [see Gehani et al. 91]. CBT presentations are not only large and complex software systems; they are also particularly likely to be modified because of various demands coming from different learners.

This paper presents an attempt to build a documentation system for a specific authoring environment: ToolBook, produced by Asymetrix; [see Toolbook 94].

ToolBook is a popular object-oriented development environment that provides a graphical user interface for creating objects, and a full-featured programming language, called OpenScript, for programming objects behavior. Programs that are associated with the objects are called "scripts". Often, a developer of a ToolBook book pays too much attention to documenting the underlying scripts, and neglects the significance of these objects. This is just one of the reasons why many ToolBook applications have ambiguous and incomplete documentation which, in turn, creates serious problems during the maintenance of the application.

This paper describes the design and implementation of an interactive documentation system, called XDoc, that supports a documentation of ToolBook applications. It promotes what we call *"on the fly" documentation* or *"on-line" documentation*, which means documenting *during* the actual development of a system. XDoc ensures that the consistency of data and information between the system and its documentation is maintained all the time, and also enables the developer to simply update the data in the documentation book by just a click of a button.

When a ToolBook developer wants to start a book and document it, he or she uses XDoc, which generates two books. These books are created from two different templates; one for the ToolBook developer to work on, named *IDB* or Interactive Documenting Book. The other book serves as the IDB's documentation book, named '*NeatDoc*'. In what follows, we will use the term 'IDB' for any user book created with XDoc, and 'NeatDoc' for a documentation book. An IDB and its NeatDoc interact with each other throughout the implementation processes of the IDB.

XDoc also allows documentation of an existing work; that is *off-line documentation*. However, this paper focuses on *on-line documentation* to further emphasize the importance of this concept in ToolBook documentation.

This paper is organized as follows: Section 2 gives a brief history of projects leading to XDoc; Section 3 is an overview of the documentation of ToolBook applications; Section 4 is a major section describing XDoc in greater detail; and Section 5 gives a case study on using XDoc for an on-line documentation of a ToolBook application.

The development of XDoc did not result in a finished product, but rather emphasis was put on the creation of a new methodology. With future work, XDoc may turn into a more complete documentation system for ToolBook books.

2. History

Our work is based on an integrated authoring environment in ToolBook, called, NEAT - *iNtegrated Environment for Authoring in ToolBook*, designed by T. Müldner, Acadia University; and S. Mayer and C. Unger from Hagen University, Germany as described in [Müldner 93a, 93b, Mayer et al. 93, Müldner 94. Müldner et al. 96]. NEAT, version 3.0 provides a template and various facilities for rapid prototyping and use of computer-based presentations called *neatware* [see van Veen 95].

The next version of NEAT, called XNeat 4.0 gave rise to XDoc. XNeat allows users to manipulate a repository of neatware and backgrounds that are created with ToolBook (for more details, see [Mahayuddin 96]).

3. ToolBook Documentation

Behind every ToolBook application there are its *object hierarchy* and its *event-driven* behavior (for more details, [see Toolbook 94]. As difficult as it is to visualize these concepts, it is even more difficult for ToolBook developers to document them in their applications; even for those who are experienced with ToolBook. This is perhaps one of the reasons why object documentation is not given much attention by programmers during the development of a ToolBook application.

Novice ToolBook programmers often have trouble finding the location of scripts since most of the visible objects they encounter do not have any script in them; experienced ToolBook developers usually put their scripts in objects of higher hierarchy, which are invisible and *incomprehensible* to novices, e.g., in a background or in a system book. Unfortunately, most of the time the location of these scripts is not documented.

Other than system variables and arrays, it is not compulsory for a ToolBook developer to formally declare the names of variables, properties, or handlers. This is an "advantage" favored by developers; particularly because most programmers find it irrelevant to declare local variables as they are only active within a handler. But, if a ToolBook developer decides not to use any system variables or arrays, what *is* there to be declared? How does a person who is trying to examine a piece of OpenScript code distinguishes a local variable from a user property, or an OpenScript keyword from a function call, if there is no way to differentiate them (unless, the programmer scans through it in the ToolBook debugger)?

Classical recommendations, adapted from documentation methods of non object-oriented programming languages, include the following:

- a head section (in comments) on top of every script of an object describing important data such as the functionality of each handlers, modifications made, and date when script was last modified;:
- consistent prefixes on the names of variables, properties and handler; for example 'sv' for system variables, such as svNumOfUnits, svUserName;
- clear comments for complicated and ambiguous pieces of source code in OpenScript.

In general, documentation that is separated from its application is usually stored in a text file that is organized in a linear way. This method is inadequate since maintainers and developers are always interested in viewing the corresponding source code at the same time as viewing its documentation as described in [Sametinger 91].

The use of hypertext solves the problem mentioned above. Hypertext makes information retrieval easier by enabling "nonsequential writing and reading". It consists of *nodes* which link or bridge the user to more relevant information by just selecting it. The information may be in the form of text, a picture, or even a video sequence [see Sametinger 91 and Instone 95].

Short4OpenScript is the only tool for ToolBook documentation, besides XDoc, that the authors have found thus far. It has been created recently by Carsten Blau, [see Blau 96], of the *Institut fuer Mediengestaltung und Medientechnologie* in Mainz, Germany and is yet to be fully developed (at the time this paper was written). Short4OpenScript creates documentation out of an OpenScript by keeping the documentation in a separate text file, and then generating an HTML-document from it.

4. XDoc

The name XDoc is actually a combination of two acronyms; **X**Neat 4.0 -- the name of the original version of XDoc, and **Doc**umentation. XDoc supports three types of users: ToolBook *developers*, who want interactive and accurate documentation for their applications; ToolBook *maintainers*, who maintain the ToolBook applications; and also *other system developers* who are perhaps interested in how the ToolBook applications were implemented.

By promoting *"on the fly" documentation*, that is documenting *during* the development of an application, XDoc maintains the consistency of data and information between a ToolBook application, and its documentation. It provides interactive access to both the IDB and its NeatDoc, hence minimizing the developer's documentation efforts.

XDoc consists of three different environments: the *XDoc Panel* environment, the *IDB* environment, and the *NeatDoc* environment. The IDB (Interactive Documenting Book) is where the *ToolBook developer* creates a new application, whilst the NeatDoc is the IDB's corresponding documentation book.

XDoc maintains a repository of IDBs and provides tools to manipulate them in the XDoc Panel, such as creating a backup for an IDB and also opening an IDB (which in turn opens its corresponding NeatDoc). In addition, it allows the user to choose which IDB to add to or to remove from the repository. This particular repository is useful for the developers to keep track of all the IDBs that they created; or those that are created by others, but made accessible to the developers. The Panel also provides tools to manipulate a repository of backgrounds, or *page templates*, mainly to be used by NeatDocs.

Developing an application out of an IDB is very much similar to developing any typical ToolBook application except that the user is given the option to document the objects created. When the developer decides to document an object, XDoc will get its name from the user, and then automatically record the necessary data in the appropriate page of the IDB's NeatDoc. The user can then either proceed to work in the IDB, or instead go to the NeatDoc to elaborate on the documentation of the object.

If the user creates a new background or a new page in the IDB, XDoc will request to create new documentation pages in its corresponding NeatDoc. For example, after creating a new background in an IDB, the user is required to create a documentation page in NeatDoc using the "Pages on a Background" template. This is because the NeatDoc will keep track of all the pages that share this background in the IDB. In addition to that, the user can also add a documentation page of type "Scripts" if it is desired that NeatDoc keep track of the script of this new background.

A NeatDoc is the documentation book for an IDB. It records everything in the IDB that the developer wants to document accurately, and it gives ample space for the user to put comments on. At the same time, it also keeps track of some of the details in the IDB which the developer did *not* choose explicitly to document. For example, a NeatDoc records the total number of backgrounds that are in the IDB, even if the developer chose to document only *some* of those backgrounds.

A NeatDoc makes the documentation tasks easier by providing various tools for the developer. For example, there is a tool to obtain the name and ID of a background in an IDB, and also a tool to create a link to the properties of an object in an IDB.

Besides recording the most current information on an IDB, a NeatDoc is also able to take note of any "old" information of the IDB. For example, if the developer had deleted an object from the IDB, perhaps because of some error, the NeatDoc does not erase the documentation of this object. Instead, it puts a side note in the documentation saying that this object has been deleted. The developer can then comment on these errors in the built-in 'Comment field' in NeatDoc. This feature is particularly useful during maintenance, or even during development because the users will be able to see more the errors made, and hopefully not repeat them.

Pages in a NeatDoc are called 'documentation pages'. Both the backgrounds and the pages have specific functionality needed for documentation; and are developed to interact with the objects in an IDB. The developer can choose the appropriate "page template" according to the portion of IDB that he or she wants to document in a documentation page. These portions are: a certain part of the book itself; a certain part of a background in the IDB; or a certain part of a page in the IDB. These parts in turn consist of things such as the user properties, the underlying scripts, the objects on a page or on a background, and many more.

Each NeatDoc environment provides the user with easy navigation and browsing capabilities similar to neatware ([see Müldner 94]). It has both the 'Control Panel', i.e., the tool for *building* the *contents* of the NeatDoc; and also the 'Table of Contents Browser', i.e., the tool for *navigating* through the *contents*. The use of hypertext in a NeatDoc enhances these capabilities further by letting the user view the data of its corresponding IDB directly from the NeatDoc.

5. Case Study - The Working System

This section provides a case study in XDoc. Space limitation prohibits detailed description of all interesting operations; instead only several important ones are demonstrated.

The first operation to be demonstrated is the creation of a new IDB. In the XDoc Panel, we first select the 'Create New' option under the menu heading 'IDB'. A dialog will pop up, providing a field to put in a name for the *new* IDB (say, "Appl" -- for "Application 1"). We will also be prompted for the names of the first background and the first page of the new IDB. (Let's call the first background "A1", and the first page "B1".) When this information is entered, we can actually see XDoc creating a new IDB using the 'IDB template'. Soon afterwards, a NeatDoc for the IDB is also created by using a 'NeatDoc template'. Specific initializations are then performed in order to make this NeatDoc collaborate with the new IDB. The new IDB, "Appl", is similar to any new ToolBook application, and is accessible to all the tools in ToolBook. The only difference between this book and any other standard ToolBook book is that the names for the IDB's first page and for its first background are already provided, and that this book also has built-in capabilities to interact with a NeatDoc, i.e., its own documentation book. Figure 1 shows the front cover page of the NeatDoc that documents IDB "Appl". Here, the NeatDoc's "Table of Contents Browser" has been opened to give the reader an idea of the kind of documentation pages that have already been set up upon creation of both the IDB and the NeatDoc.

Figure 1 A New NeatDoc created for an IDB

Next, we create new system variables for "App1". Two system variables were created: sv_UserCount, for the purpose of counting the number of people who use IDB "App1"; and sv_UserNames, to record the names of these users. Once the variables are created in "App1", we can move to its NeatDoc, and click on the 'Update Page' button that is available in the 'System Variables' documentation page.

If a system variable; for example 'sv_UserNames' has a value that could not fit in the one-line field provided in the NeatDoc's page then, we can double-click on a line where this value is located, and a 'View Box' will pop up displaying the full contents.

We proceed through this case study by discussing the documentation of graphical objects. Specifically, we will create a few objects on background "A1", i.e., the first background in "App1", to *greet* a user when he or she enters the IDB. First, a rectangle is created for decorative purposes; and therefore is not documented. A text field, named "Welcome", is then added to welcome the users.

Now, we will add a new button, named "GreetingButton" to the background and then put a script in it, so that the user can get a greeting of "Hello World!" when he or she clicks it. We also want to create a link from the IDB to the script of this button. To do so, we can use the menu option "Create Script Link" to create a hypertext link to the underlying script of the button in the IDB.

6. Summary and Future Work

ToolBook developers have had difficulties in finding a documentation method that matches their needs in developing an application. XDoc was implemented with the intention of supplying a tool to assist these developers. It allows them to document their applications on-line, in a standard and an easy way. XDoc minimizes developer's documentation efforts by providing an interactive access to both the application book and its documentation book. In addition, the use of hypertext links promotes data consistency between the two books.

Much more work could be done to further enhance XDoc's capabilities. Below, we describe some suggestions for future implementation. Documentation operations of XDoc, in its current form, are not fully automatic even though both the IDB and NeatDoc *are* interactive. With a considerable amount of work, new

BEST COPY AVAILABLE

and appropriate documentation pages in NeatDoc could be created as soon as they are needed by an IDB. A link from each of these pages to the appropriate object in IDB could also be assigned at the same time. NeatDoc pages of type "Pages on a Background" currently do not keep track of a deleted page. Similarly, pages of type "Backgrounds in a Book" do not keep track of a deleted background. A deleted page or background has to be documented manually by the developer. These problems can be easily fixed by adapting the implementation used in pages of type "Objects", "System Variables" and "User Properties", i.e., by using an array to hold the information about these pages or backgrounds, and update it when necessary. For the NeatDoc pages of type "Scripts", it would be useful to add the capability to scroll automatically to a specific portion of code, before it is displayed in a 'Script Box' for viewing. This can be easily implemented by providing a tool to create hypertext links in the 'Comments' field. A user would first select a few words from the comment field, and then activate this tool, which would then ask the user which portion of the script a 'Script Box' should scroll to. By incorporating this information with a "ready made" script, the words selected can then be made a hypertext to link and scroll to the specific portion of the script. A developer's documentation efforts could be further reduced if all the tools that a NeatDoc provides were available on a 'toolbar', or a 'palette' instead of using menus. This feature would be easy to implement. Finally, since both an IDB and its NeatDoc depend on each other for having consistent data, future implementation that enhances the security for these two books would be desired. For example, XDoc could prompt the user to save both books when he or she chooses to close only one of them.

Abstract: This paper describes an innovative project between the Australian Centre for Computer Enhanced Learning, IBM Australia Ltd. and the Royal Children's Hospital School, Melbourne, Australia. Described are two case studies of children involved in the project, with a summary of the impact new and emerging technologies have on children in exceptional circumstances.

The initial aim of the project was to make communication and contact between hospitalised and homebound children, and their peers, as normal as possible. The use of multimedia, Internet, the World Wide Web, and video conferencing, were seen as valuable ways of achieving that aim.

INTRODUCTION

The emergence of Multimedia Computing that enables the integration of video images, sound, graphics and text has changed the way young people learn things. In Multimedia computing users control the computer presentation by controlling the rate and selection of media being presented. In addition to providing interaction to the user, multimedia provides opportunities for users to make their own choices and direct their own experiences. Though there is no conclusive research evidence, several studies have indicated that multimedia improves student learning and teacher presentations [Toomey, Mahon & Thalathoti 1993; Toomey, Mahon & Thalathoti 1994; Kozma 1994].

Widespread new application areas of Multimedia computing include video conferencing, virtual reality simulation, computer aided learning, and distributed and networked multimedia over the Internet. These applications play a potential role in every field in society including education, training, business and recreation. Multimedia also helps to improve the lives of people with visual, mobility, speech, language and learning impairments with the help of special gadgets such as touch sensitive screens, head pointers, mouth sticks, speech synthesizers, modified keyboards etc. [Castorina 1994].

There is group of young people who cannot attend schools on a regular basis due to illness or injury, and who spend most of their time either in hospital or at home. ACCEL, with the help of its major sponsor, IBM Australia Ltd, has set about enhancing the quality of life and learning opportunities of these sick and disabled children, while attempting to understand the learning and teaching potential of the new and emerging technologies.

Starbright World, a nonprofit organisation developing interactive entertainment for ailing children, in its research on long term hospitalised children, showed a diminishment in the need for pain medication when only simple audio-visual equipment was provided for the children to use. In addition to relieving pain and stress, Australian Centre for Computer Enhanced Learning (ACCEL) has been helping sick children keep up to date with what is going on in their school. With this focus, ACCEL researchers have used the following questions to inform their work: Can multimedia help a sick child or a long term patient-student to:

- recover from illness?

- reduce the monotony, boredom and isolation at hospital/home ?
- keep in touch with his/her peers and school ?
- improve self-esteem and self-confidence?
- continue on the path of academic and social learning?

THE PILOT PROJECT

ACCEL, in partnership with the Royal Children's Hospital School, Melbourne and IBM Australia Ltd., developed a pilot project using multimedia video conferencing to link hospitalised and homebound children with their schools of origin. This technology (involving audio, video, graphics and text) operates over telephone lines and enables students to remain in close contact with school whilst learning new and creative technological skills. It is the intention of the project to provide the best possible avenue of opportunities for regular live visual contact between hospitalised and homebound students and their schools of origin.

The pilot project used *Person to Person*™ (P2P), a desktop multimedia video conferencing system developed by IBM. Desk-top video conferencing allows remote desk-top personal computer users to see each other, conduct meetings and work together on collaborative projects. P2P is very popular and has applications in the areas of Distance Education (Augusta Tech: Georgia and University of Michigan), Interactive Video Advising (Pima Community College, Arizona), Industry (Ford Motors at Michigan, Spain, UK) etc. To facilitate a link between a patient-student and another site using P2P, two personal computers are required with the following minimum configuration:

HARDWARE:

486 CPU 33 Mhz with a hard disk, 8Mb RAM, VGA or SVGA colour monitor, Mouse or Touch sensitive screen, Video camera/Camcorder, 14.4 kbps Modem, Action Media II video capture and playback adaptor, access to telephone line(s).

SOFTWARE:
OS/2 Operating system or Windows 3.1 /Windows for Workgroups and Person 2 Person for OS/2 or Windows.

PERSON 2 PERSON SOFTWARE

Person to Person has a number of features that make "electronic collaboration" as easy as dialing a phone or drawing on a chalkboard. The software includes shared talk and chalkboards, video conferencing, file transfer etc., as in Fig 1.

BACKGROUND TO THE PILOT PROJECT

The original intent of the P2P project was to use multimedia technology to link long term hospital bound children back to their classrooms in their school of origin. This program will not replace the school, but it is believed that the program brings many benefits to a sick child. The aims of this project are to (i) enhance learning opportunities, (ii) provide immediate, direct contact with the school of origin, with other students and designated sites both academically and socially, (iii) enhance self esteem and self confidence, (iv) develop skills in on-line communication with other children, (v) provide an opportunity to gain a degree of control and 'normalisation' over part of their life through continuing their education.

During 1994-95, the project team investigated the potential of placing personal computers equipped with the necessary hardware and software in the Burns, Oncology, Orthopaedic and Neurology wards of the Royal Children's hospital and it soon became apparent that this was going to be difficult for three main reasons: (a) the technical logistics of the installation of the necessary equipment on these wards are daunting, (b) the demands of medical care and treatment interrupted stable links into schools and was too disruptive to timetables, (c) the reduced and unpredictable stay of student-patients; at the point when they could make best use of P2P, they were discharged to recuperate at home. This raised questions of cost-benefits and the issue of where the technology could be best utilised.

The P2P project team became aware of another group of children who are chronically ill and homebound and who are educationally linked into the Distance Education Centre, Victoria. Some of these students have at various times a dual enrollment with the Royal Children's Hospital School and Distance Education Centre. In view of the shared aims and common objectives in meeting the educational needs of these student-patients, Distance Education Centre was invited to join the P2P project. Another advantage of this involvement is that the Distance Education Centre can provide a stable environment together with current curriculum with an opportunity for flexible staffing.

PROJECT CASE STUDIES

Two long-term patient-students *Chris* and *Anthonella* have been selected for the P2P project. Both were in Melbourne's Royal Children's Hospital for some time and later sent home. Both children will require special medical attention for their whole lives. These two case studies will be used to evaluate and refine the project for future years. Both Chris and Anthonella were given similar hardware and software that meets the configuration explained earlier. The majority of this equipment and software was donated to the project by IBM Australia Ltd.

Chris , aged 10, has a severe uncategorised physical disability. He is the only known child worldwide with this condition. Although there is no name for his condition, some of the symptoms are similar to cystic fibrosis. Chris has a chest wall deformity, a small lung, severe scoliosis, and was born with missing ribs on his left side. His main problem is that his kidneys bind together on one side. Chris was able to attend school from his first year of schooling to the middle of his third grade. Chris's condition later deteriorated and his time in hospital has become unpredictable. Chris was unable to attend school as he required oxygen twenty four hours a day, and he tires easily. Another reason for Chris's inability to attend was due to his high chance of infection. Even so much as a common cold could hospitalise Chris for three or four weeks at a time. Although Chris cannot attend school on a full time basis, he would like to attend for a few hours per week. Until this option is a reality, his intellectual needs are being satisfied by a visiting teacher who sees Chris twice a week.

Due to Chris's inability to attend school for a number of years, his views about the importance of learning have not advanced far. He was keen to play games, but lacks motivation in areas covered by the curriculum in most schools. Through using P2P in conjunction with Dundee South Primary School, Chris was able to correspond with his classmates and see what was going on in his classroom. Linking to the classroom has proven to be very positive with Chris.

It was clear in Chris's case that the interaction with peers was able to show him many things about his own abilities, particularly that he was able to learn the skills needed to operate apparent complicated technical equipment, that then gave him contact with other children. He was also very keen to play computer games, which help to occupy his time and entertain him, in much the same way as his age group peers.

We must sadly report that Chris passed away late in 1996.

Anthonella, aged 12, has Xeroderma Pigmentosum, a rare incurable congenital condition in which her skin and eyes do not have the capacity to repair the damage caused by Sun light or Ultra Violet light. She attended school until 1990 but despite the best efforts of the school she was unable to continue due to the development of potentially fatal skin cancers caused by the high level of exposure to UV light under normal school conditions. She was at risk due to the high level of exposure to UV lights in the school buildings and sunlight could not be effectively screened out. Now, she cannot attend school, visit a playground nor even go out of the four walls of her house due to exposure to the sun's UV rays. Her skin is even sensitive to neon, and halogen lights. Her schooling is now in her own home under a 60-watt incandescent electric bulb. "A lot of the time I feel I am alone in the middle of nowhere, with nobody" says Anthonella. Anthonella is a very able and conscientious student. However, her isolation has impinged on her educational progress and she has been in danger of falling further behind her peer group in both educational and social skills.

Since 1991, Anthonella has been restricted to her home and has continued her education through the Distance Education Centre, Victoria with a weekly visit from the visiting teacher service. Anthonella's personal computer is fitted with a special anti-radiation screen in order to avoid her being exposed to the radiation emitted by the computer's video display unit.

She is a highly intelligent young girl whose forced isolation was having a major negative impact on her self concept. She was able to see the long term issues for herself of her isolation. It was impossible for her and indeed her very supportive family, to see a worthwhile future. After the implementation of this P2P project Anthonella said "This has changed my life. I like this program so much I spend all day with it. I just do not remember what I used to do if I didn't watch television". This dramatic sounding response is becoming increasingly more accurate for Anthonella. Her view of herself and her world has changed. She sees her developing skills as offering her a window to the outside world now and potential employment from home in the future. She is now considering a variety of occupations for herself, with the full realisation that she is a "night person", but not letting that fact limit her imagination.

Not only is she rapidly catching up to her school-based peers educationally, but emotionally as well. She has gained confidence and now speaks fluently to people she meets both personally and virtually. While her normal academic learning is progressing well, she is becoming highly proficient as a user of technology, in a very real way, doubling the learning required for her school-based peers who do not have access to the technology that Anthonella has.
With the P2P project, Anthonella can now access directly the Distance Education Centre via the multimedia technology, link with other home bound students, and be a more active participant in her studies and gets the desperately needed social interaction with her peer group. She also now has an email address through Victoria University of Technology, and regularly corresponds with university researchers.

PROJECT CONSTRAINTS

Several constraints were encountered while using the P2P conferencing:

1. Live video between the patient-student and the school is very slow over telephone lines. Real time video requires the transmission of 20 to 25 video frames per second. Even with a fast modem (28.8kbps) it is possible to send only 2 to 3 frames per second over the existing telephone lines. Again, to use the audio link, a second telephone line is required. These problems (video frame rate and audio link) could be solved to some extent by using an ISDN connection. However, the other utilities of Person to Person program including the *File transfer*, *Still video*, *Talk* and *Chalk board* work effectively with the existing telecommunication technology.

2. The Dundee South Primary School has only two telephone lines connected to the school, one to the office and the other to fax machine. Whenever the school wants to link up with Chris, they have to disconnect

the Fax machine and use that line to establish a connection. This interrupts the normal school office functions. An additional dedicated line is required for reliable communication with Chris.

3. Support for extension and maintenance of the project: IBM Australia Ltd., generously donated hardware and software, and have been very supportive in a long-term ongoing fashion. Additional funding is required for charges associated with telephone lines, printers, computer specific furniture, video cameras, modems, software etc.

FUTURE OF THE PROJECT

Much of the success of this project rests with the motivation of the patient-students involved. This had led the project team to question current classroom pedagogy and its appropriateness to these children, and indeed any implications this may have for all children in conventional settings.

We have noted profound enthusiasm in the children on the project. They are self motivated when they do not have other classroom-type tasks to perform, and, of course, are also very able in their completion of set classroom tasks. The research team is currently considering alternative approaches to learning that access to this specialised technical equipment allows for the first time in history. These children have already developed technical skills far surpassing the vast majority of primary school teachers in Australia. Their own future employment prospects probably will rely on their expertise. It therefore seems appropriate that they are given different options to learning styles than what is on offer in mainstream Australian schools. We feel that connection to Internet and the World Wide Web in its emerging form, will offer many things to these children, and have therefore given access to it.

Internet is growing at exponential rates and is easily accessible by anyone from anywhere in the world. It is assumed that by using the Internet services a patient child can turn the hospital room into a playground, a classroom or a family home. Access to Internet services is provided through a dial-up service at Victoria University of Technology using Serial Line Internet Protocol (SLIP) as shown in Fig 2. The hardware and software for the patient-students will soon be upgraded to give maximum performance under normal conditions and they will be trained in how to use the new equipment and software, although their expertise with the current equipment suggests that little training will be necessary. An *Internet Filter* will be installed, in consultation with the children's primary care givers, on both the machines to filter out any obscene and sensitive information arriving at Anthonella's computer via Internet.

The advantages of linking Anthonella to the Internet are many. For instance, using *Electronic-mail*, Anthonella can communicate electronically with friends, peers, teachers, and also with Royal Children's Hospital School and the Distance Education Centre. They can virtually meet other patient-children, share their experiences, exchange messages about their illnesses, or play on-line games. They can participate in collaborative projects through discussion groups like International Electronic Classroom Connections, K-12 projects etc. Currently, Anthonella is "voting" for email by using it frequently. We have informed Anthonella that we keep records of everything she sends us, and she has been very obliging. Her first message read "Just sending you a test", and her most recent message was a full page of text. The longest delay between messages has been two days. It is obvious by her use of this facility that she loves it.

Using *Telnet*, Anthonella can widen her knowledge by remotely logging into worldwide Databases, Libraries, NASA, and other locations. *File Transfer Protocol* allows her to send and receive assignments from school, and with *Internet Phone* she can conduct inexpensive real time audio conferencing with specialists anywhere in the world.

The P2P video conferencing may be supplemented with *CU-SeeMe* on Internet. *CU-SeeMe* is a free video conferencing program over the Internet that allows desktop video conferencing with another site located anywhere in the world. Unlike P2P, it includes audio and to receive video no additional hardware is required. The video transmission (frame rate) is dependent on the IP network traffic. Using this technology, Anthonella may be linked to her school/Distance Education Centre to have real classroom experience and to interact with teachers and peers in real time.

WorldWideWeb (WWW) is enhancing knowledge and learning opportunities through its hyperlinks to worldwide multimedia databases, hypermedia documents and virtual reality projects. Anthonella hopes soon to create her own home page on the web using HTML. She can participate in on-line interactive projects such as the *Interactive Frog Dissection Project* on WWW or connect to *Starbright World's* interactive, multiuser, point-to-multipoint network to talk and play with other children irrespective of their physical condition or geographical location and share *Starbright's* interactive, virtual reality environments. Currently, however, Anthonella, as any normal little girl, is keen to discover pictures of her favourite movie stars. And they are all male! The desire to gain this specific information in itself has ensured her asking lots of technical questions to develop skills she requires to solve her immediate problems.

ACCEL Server

Figure 2. Internet access for Anthonella via ACCEL server

It appears, therefore, that the children on the project will require continuing training in the use of new equipment and software. These are their learning tools. Given these tools, particular content for their learning can be an area for local negotiation. The research team will be looking at these issues in the coming months.

CONCLUSION

The P2P multimedia project seems to be especially significant for young disabled students like Anthonella where the disability is not temporary like a broken arm, yet may not be immediately life threatening. It is envisaged that with the successful development of the P2P project and the support given by ACCEL, IBM Australia Ltd., Royal Children's Hospital and Distance Education, Anthonella having completed her primary education and commenced her secondary education this year will eventually have access to a tertiary qualification. In the long term there is also the potential for Anthonella to develop a career and open employment opportunities (which could operate from a home computer), given that she will always need to live and work in a highly protected environment.

The P2P project is pushing the barriers of new technology to enable people in a variety of circumstances to have access to open learning and employment opportunities which are currently not available to them. It is humanitarian in its ability to change the lives in a most positive fashion of sick and disabled children. The project is limited only by the availability of finance to support the acquisition of equipment and expertise to facilitate its wide spread implementation.

ASML: Web Authoring by Site, Not by Hindsight

Charles B. Owen and Fillia Makedon
Dartmouth Experimental Visualization Laboratory (DEVLAB)
Dartmouth College, Hanover, NH, 03755
Email: cowen@cs.dartmouth.edu, makedon@cs.dartmouth.edu

Abstract: This paper describes Automatic Site Markup Language (ASML), a revolutionary new web authoring system. ASML is a markup language designed to support web authoring at the site rather than just the page level. Often web-site designers find themselves plagued by hindsight as they wish they had chosen a different page layout or navigation graphic. Educational users in particular find it difficult to define at the beginning of a project just what a site will look like and how it will evolve. ASML provides a single solution for site level authoring wherein common content exists in only one place. It also provides for logical rather than physical organization of projects, simple searching and indexing, and CGI scripting without resorting to custom programming. Support for derivative sites is a unique feature which is very useful in classroom support environments.

Introduction

The World Wide Web (WWW or web) has become a valuable tool for the distribution of educational materials. Class notes, tutorials, and lectures can be electronically distributed at low cost. However, authoring these materials in a high-quality form can be time consuming and frustrating. Page layout, common graphical elements, and site structure become integral parts of hundreds or thousands of web *pages* and are difficult to change. Custom programming is required to make simple corrections, handle form data, or provide any sort of dynamic content.

The Dartmouth Experimental Visualization Laboratory (DEVLAB) has been involved in electronic publishing since its inception and has produced several large scale web projects including *The Ancient Olympic Games Virtual Museum* [DEVLAB 1996], and *The Prehistory Archaeology of the Aegean* [Rutter et al. 1996]. This experience led to the development of Automatic Site Markup Language (ASML) [Owen et al. 1997], a new markup language for the production of World Wide Web *sites*, not just pages. ASML treats a web publishing project as a single large document rather than a collection of disjoint pages. It centralizes common functionality, decreases redundancy in the site description, and replaces many uses of scripting languages and other programming efforts in site construction. It is a single, cohesive, tool providing authoring, scripting, searching, and indexing features. This paper presents an overview of ASML and its use in courseware production. A complete description of the system is available as a technical report [Owen et al. 1997].

In ASML terminology, a *site* is a single web production. As an example, the Prehistoric Archaeology of the Aegean is considered a site, even though it coresides on a server with other web publications. The ASML terminology for a complete server is a *server-site*. [Fig. 1] illustrates the use of ASML at a site. ASML format content, as well as imported content (images, RTF, HTML), are processed to produce the site publication which is served in conventional forms. ASML does not introduce a new distribution standard at all. It also inflicts no performance penalty. Production of web sites using ASML can be likened to producing documents using a word processor, where the author does not edit the final document format at all (Postscript, for example), but rather edits an intermediate format (Microsoft Word). The conventional approach of producing a site as individual HTML pages is very much like directly editing Postscript to produce pages. More precisely, it's like editing one Postscript document per page. This page-at-a-time approach severely limits global site changes. Inevitable reformatting and content restructuring requires computer programs which iterate over all pages of the site and make changes. It is common to hear authors say that they are unhappy with a graphic in their site and wish they had chosen a different one in hindsight. ASML allows a site to be described *logically*, with common elements stored in one location, so reformatting a site requires minimal changes to site *templates* and a rebuild

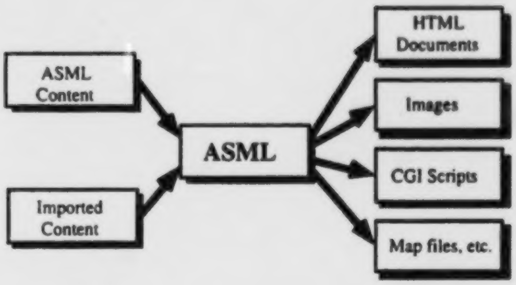

Figure 1 - Use of ASML at a site

of the site (which is automatic and takes only a few seconds). This approach is called *site-level authoring* and is a basic feature of ASML.

There are many site-level authoring approaches. The most common is the production of scripts in some programming language which either edit all content in an existing site, produce a new site from raw data, or generate a site from content hard-coded into the programs. The Perl programming language [Wall & Schwartz 1991] is a common tool for this task due to its wide availability and block quoting capabilities. Other systems include Frontier from UserLand software, a popular Macintosh Environment [UserLand 1997]. Use of these systems is summed up by Hall and Tews in a MacWeek review of Frontier: "Scripting in Frontier is by no means a job for beginners..." [Hall & Tews 1996].

Carl Davis has created a large list of graphical HTML editors with reviews [Davis 1996]. Site-level features are rare in editors, the majority of which are designed for single page editing. Web Project Explorer from Haht Software incorporates a system of "Clips", which are very similar to ASML templates [Haht 1997]. However, clips are static macros which contain fixed content, as distinct from ASML templates which allow variable content. Web Project Explorer has site level organization and visualization tools, but retains a page-at-a-time editing and composition approach.

A large number of education specific approaches to site-level authoring and automatic content generation have been devised. ANDES Text Markup Language (ATML) is a markup language, much like ASML, but is specific to the ANDES distant education system [Johnson et al. 1996]. CourseWeaver is an Apple Hypercard-based system designed for development of courseware for the web [Rebelsky 1997]. It uses a custom markup similar to that of ASML, provides for multi-targeted output, and handles content input translation. ASML was designed with many of the same objectives as these systems, but is not specific to education or any other application, and, as such, does not enforce any standard page layout, navigation mechanism, or site structure.

ASML Features

ASML has many features. This section provides an overview of some of these features and describes how they apply to educational users of the web. ASML is an integrated system, not a collection of programs. The following features are all integral parts of the ASML environment.

Simple Markup Format

ASML uses a simple markup format designed to be familiar to the HTML user. ASML does not supplant or replace HTML. HTML can be freely used in ASML documents. HTML is a very fluid standard. Graphical editors often attempt to hide markup from users with limited success. ASML does not introduce that limitation. Instead, ASML can be considered an *extension* of HTML. ASML functionality can be added to an existing page by simply adding ASML markup. The page is then processed to produce the published HTML version.

ASML uses a markup format of tags, end tags, attributes, and values identical to HTML except for the use of { } as markup delimiters rather than < > as in HTML. HTML and ASML can freely coexist in the same document and are easily distinguished. An image inclusion in HTML and ASML might use the following tags:

```
<img src="/bronze/images/bar.gif" width=400 height=10 alt="---" align="center">
{img src="/images/bar.gif" alt="---" align="center"}
```

The structure of the tags is very similar. The differences are related to the automation features of ASML. The width and height attributes are determined automatically and need not be included. The image source in ASML is relative to the site directory tree, not the server directory tree, a characteristic of *location independence*.

The term *expand* will be used throughout this document to indicate the processing of an ASML tag. Every ASML tag is expanded and no ASML tags remain in the output (except when specifically added using an escape mechanism). Browsers need not be modified to support any ASML syntax. Indeed, ASML is invisible to the WWW user. Some ASML tags have conditional and repetitive processing functions and some tags expand to empty content.

ASML comment sequences are delimited by `{--` and `--}`. Comments are completely ignored by ASML. They are not translated to HTML comments or reproduced in any way in the output page. HTML comments are often underutilized due to the fact that any user can view the source of a page and see the comments and they increase the transmitted file size. ASML comments are available to the site author, but not the casual user. Question solutions or personal notes can be placed in comments with no fear that students will "view source" and read them.

The markup format is easy for an HTML user to learn, but does represent a tradeoff. It conflicts with the use of braces in cascading style sheets [Lie & Bos 1996] and JavaScript [Netscape 1996]. An escape mechanism is in place to accommodate this usage, but is somewhat cumbersome to use. A future extended quoting mechanism is under consideration for simplifying this usage.

Templates and Site Level Content Generation

Web sites contain large amounts of redundancy. Navigation methods and page appearance are kept consistent. Graphic elements are used repetitively so they will stay in the browser cache. Ideally every site development project would define these elements up front. Skeleton pages could then be used to create the site. However, content acquisition often proceeds in parallel with style and format design and some sites, particularly educational sites, are subject to indefinite evolution. And, of course, there's always someone who hates the purple graphic and wants it changed in all 318 pages.

Templates are the mechanism in ASML for defining repetitive content. A template can be created for a graphical element, page elements, entire pages, or entire sites. A template is very similar to a macro. A template expansion in ASML is initiated with a tag, for example: `{pagetop title="My Home Page"}`. Parameters on templates allow variable content. Templates are defined using the `{define}` and `{append}` tags. An example template usage might be the definition of a template for a graphical separator in a site. The ASML markup for such a template definition might be:

```
{define name="separator"}{img src="/image/sep.gif"}{/define}
```

This template could then be placed at any point in the text using the `{separator}` tag. The `{define}` tag need be at only one place, often in a file which defines format elements for a site. Changing this one line changes the separator everywhere it is used.

ASML templates are more than simple parameterized macros. They can store variable content, implement counters, and include conditional and repetitive content. Content can be multi-targeted using templates, so it is very easy to construct an automatic table of contents. Multiple simultaneous tables of content can be used in the same site and can be formatting in any form desired including tables and graphical bullets.

Logical Modularization

HTML enforces a specific organization of site content. A file is equivalent to a page and groupings of content are physical groupings, typically defined by the directory structure. Large numbers of small files can be difficult to manage. Any site can be represented as a single ASML file. However, it is usually much more efficient to break this file into smaller, more manageable units. The big difference is: the modularization can be *logical.* One file may contain format elements which are common for a site. Another may contain all content on a given topic, even though the final site will divide that content among three pages. Logical modularization allows a site to be broken into components which are sensible for the user rather than the delivery mechanism.

Derivative Sites

Educational sites are often *derivative sites*, sites where content is derived from an alien format. The Prehistory Archaeology of the Aegean site is an example derivative site. This site is based on a large set of class notes by Prof. Jeremy Rutter of Dartmouth College. The site is meant to be supplemental to the notes which are also provided to students in a bound form. The web site presents the same material, but is searchable, provides the images in full color, and has links to other content. The class notes are expanded regularly and Prof. Rutter wishes to maintain them in a word processor format (Microsoft Word) so that they can be easily printed.

ASML supports *imported content*, content supplied in forms other than HTML or ASML. In the DEVLAB production of the Prehistoric Archaeology of the Aegean, the content is provided as Rich Text Format (RTF) exported from Microsoft Word. That content is imported into ASML when the site is generated and used to construct the pages. The original Word document becomes a source for compilation of the site. Whenever that document changes the site can be rebuild, completely incorporating the changes. This is importance in any application where content routinely changes and must appear as both paper and web documents. A derivative site is distinct from a *translated site* in that the content in a translated site undergoes a one-time translation to HTML. Later revision of the content requires either a new translation or a manual search for the changes.

Multi-targeting and Location Independence

Multi-targeting is the ability to produce identical content in more than one format. Providing both a "frame" and "frame-free" version of a site is an example of multi-targeting. ASML allows content to be shared among multiple formats freely and, therefore, supports multi-targeting. *Location independence* is the ability to produce a site at any required server address. This is a basic feature of ASML. Using the `{base}` tag, content can be relocated at will. In several DEVLAB projects this feature has been used to maintain simultaneous development and publication sites for the same project. The published site was updated occasionally when the content reached stable milestones. The development site contained content in incomplete stages. This feature is also useful when sites move from a development server to a publication server.

Content Indexing and Searching

ASML has a built-in indexing system and search engine. Indexing a site requires only the addition of the `index` attribute to page generation and a single `{index}` tag specifying the file name for each index. Multiple indices can be constructed for a site allowing content can be categorized. As an example, the Prehistoric Archaeology of the Aegean site has three major categories of content: lesson text, images, and bibliographies. The ASML search engine is easy to implement using only ASML (no Perl scripts or other alternative tools).

The ASML search engine is based on an index file constructed when the site is built, allowing for very fast search operations. Search results are obtained quickly with minimum load on the web server. The search engine scores pages which match the query and ranks the pages in descending relevance. A unique feature of ASML is *search highlighting*. A page located using the search engine can be accessed with all search terms highlighted in red. In addition, the browser is automatically advanced to the first search term located in the document.

Simplified CGI Scripting

Beyond the programming world the term *Common Gateway Interface* (CGI) strikes terror into the hearts of developers. HTML is highly intuitive, easy to learn and use, and very forgiving; Perl is not! But, scripting is necessary for the generation of dynamic content and processing of data forms. ASML can serve as the sole scripting mechanism in many applications. Production of a script is little different from production of a page. Form variables are automatically acquired and converted to templates by ASML. All issues of CGI protocol are managed by ASML, requiring no user knowledge of the underlying mechanisms.

A Brief Tag Summary

A complete list of ASML tags is beyond the scope of this paper and is available as a technical report [Owen 1997]. There are over two dozen basic tags and this set is easily expanded using the template mechanism. The tags can be grouped into several categories: template management (`{define}`, `{append}`, `{definelist}`), environment (`{base}`, `{include}`, `{page}`), CGI and form support (`{formget}`), searching and indexing (`{index}`, `{search}`, `{highlight}`), conditional and iterative execution (`{if}`, `{else}`, `{foreach}`), HTML enhancement (`{img}`), and derivative content (`{import}`, `{section}`). (Not a complete list.)

Courseware Production using ASML and an Example Site

DEVLAB development of ASML has been driven by real-world applications. Many DEVLAB web projects involved first year college students with no experience in programming or HTML. Skilled programmer labor is often difficult to come by due to the demands of many research projects. Every effort has been made to move programming labor from site-specific detail to the general ASML environment and provide a user interface that students with negligible experience can comprehend and use.

The Prehistoric Archaeology of the Aegean

A major courseware project at the DEVLAB has been the Prehistoric Archaeology of the Aegean [Rutter et al. 1996]. [Fig. 2] shows two pages from this site. This project uses nearly every feature of ASML and is an example of ASML use in courseware. It also provided a large amount of user testing. The site includes 29 detailed lessens in archaeology and is designed for student use. Over 500 images of archaeological digs, historic locations, and significant artifacts are included in the site. All images are presented in a small browsing format, a larger display format, and the full high-resolution scan size.

The site is a *derivative site* and can be reconstructed as the content is updated (indeed, it has been updated several times). The content is imported as RTF text. The ASML search engine is an integral feature of the site and four indices are generated. The pages which present the images are generated dynamically by an ASML CGI script. The page layout and navigation mechanisms were changed repeatedly in the process of site development. In spite of the fact that this site incorporates more than 100 pages, it is produced by 14 ASML files with a total of only 1759 lines. Over a third of these lines are a list of the available images.

Summary

Courseware authors need new approaches to World Wide Web development which eliminate redundant effort and allow sites to be created as coherent documents, not collections of pages. ASML is one such approach. While retaining the simple and well known structure of HTML and total compatibility with existing technology, ASML provides numerous high-level facilities including centralization of common page elements, derived sites, and indexing and search. Use of these features is painless and an HTML user can expand to ASML functionality with minimal effort. In many cases ASML can replace custom programming in site development. ASML is currently in version 1.03 and many new features are planned. More information on ASML can be found at `<http://devlab.dartmouth.edu/asml/>`.

Point-and-Click Construction of Comic Actor Animation Sequences

Knut Manske and Max Mühlhäuser
Telecooperation Department
University of Linz, 4040 Linz, Austria
Email: knut@tk.uni-linz.ac.at, max@tk.uni-linz.ac.at

Abstract: Adding animated comic actors to courseware is usually very time-consuming and tedious and requires expert knowledge. Using our approach, this task becomes a matter of simple point-and-click actions.

Only once per character, a professional graphic artist must create a set of elementary animation sequences conforming to our approach. From then on, any courseware author can graphically specify an entire storyboard using our Comic Actor Sequence Editor (caSE). caSE uses a sophisticated approach for combining the elementary building blocks into a complete animation.

Our comic actors can be integrated with multimedia documents, but also with arbitrary interactive software, e.g., help agents. Using a digital chroma keying technique, our Comic Actor Playing Engine (caPE) displays the animation transparently on top of any graphical user interface.

The system runs under MS Windows; a first version is used in a public interactive exhibit about animation techniques and shows excellent performance.

1 Introduction

A primary concern in computer-aided instruction lies in both the effort and expertise required to create instructional material. The learners' expectations raised by the word "multimedia" may boost the relation of authoring time to courseware unit length (in hours) by another order of magnitude. Even worse, decent multimedia courseware authoring requires subject matter experts, artists, and computing experts to cooperate. Many courseware authors are unable to organise or finance such a coordinated effort.

Animations have often been viewed as the most valuable time-based media to be integrated into courseware, being more effective than live video and audio. But animations can not only illustrate technical processes, they can greatly enhance learner motivation, interest, and retention rate. In particular, animated cartoon characters can be used in numerous ways, both as part of multimedia (courseware) presentations, and as an add-on to software user interfaces (e.g., as part of the online help system).

In order to greatly reduce the effort required to create animations, we developed a two-step concept and implemented it with a focus on animated cartoon characters which overlay other presentations (documents or software user interfaces):

- First, an artist creates generic building blocks for a certain class of animated cartoons.
- These building blocks are integrated into our comic actor sequence editor, caSE. caSE can then be repeatedly used by numerous subject matter experts in order to build custom animated cartoons. This activity is reduced to a number of easy-to-learn graphical ("point-and-click") actions.
- At runtime, our comic actor playing engine, caPE, displays the animated cartoons synchronously with the underlying multimedia document or software user interface. caPE is based on a "digital chroma keying" approach and is conceived such that interoperation with arbitrary software or presentation tools can be achieved.

1.1 Structure Of This Paper

In the following section we are reflecting on the state of the art. In the remainder, we will describe the general concept of generic building blocks for animated sequences (in this case animated cartoon actions) and their composition ([Basic Concept]).

The sections [caSE: A Generic Comic Actor Sequence Editor] and [caPE: The Comic Actor Playing Engine] describe the caSE editor and the caPE engine, respectively. A summary will conclude the article.

2 Related Work

Gibbs and Breiteneder [Breiteneder & Gibbs 94, Gibbs et al. 93] discussed the use of video widgets in the form of video actors. They used a hybrid analog/digital system and a layering technique that is very expensive to implement as digital-only. Their straight forward building-block approach was provided as a C++ class "VideoActor". We preferred affordable digital-only technique since we target MS Windows™ PC typical for CAL teaching environments; we rather concentrated on a more sophisticated automated building-block approach.

The construction and integration of digital actors is described by Magnenat Thalmann and Thalmann [Magnenat Thalmann & Thalmann 95]. The use of facial animation is also discussed there. Owen and Willis [Owen & Willis 94] are modeling and interpolating cartoon characters using NURBS. These approaches focus on specialized, closed-shop presentations and usually require powerful graphics tools.

We saw our main task in integrating comic actors with separate applications and with the graphical user interface. Therefore, we left the problem of drawing and animating to specialists, and concentrated on the composition of custom animations from building blocks.

Cartoon characters as help agents become more and more popular (cf. MS Office '97™ and Lotus Notes™). Such characters, however, are custom designed in a huge effort and nevertheless usually "sit in a corner of the screen" instead of walking to and pointing at UI objects.

Multimedia authoring tools such as Macromedia Director™, IconAuthor™ etc. include animation support, but only at the "low" technical level which our approach limits to the professional designer's task. User-friendly notion of story board actions and intelligent combination of building-blocks into such actions as with our caSE tool are not intended.

3 Basic Concept

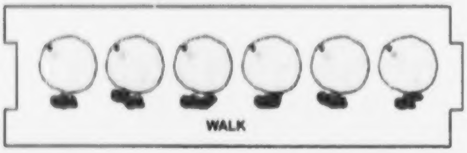

Figure 1: Illustration of the 'walk' building block [1].

The basic pieces of animation that are used as building blocks for complete animations are created by graphic artists. These animation sequences have to provide exact matches to other sequences.

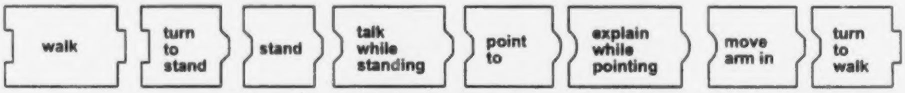

Figure 2: Some example building blocks with matches.

This way an author can, e.g., create a walking sequence by using the building block 'walk' (one step) repeatedly. Based on the distance between two points on the screen and the distance the actor advances in the animation sequence, the number of necessary repetitions of the sequence can be calculated. The animation for walking (some steps) between these two points can be created automatically.

---

[1] This comic actor represents an Upper-Austrian dumpling.

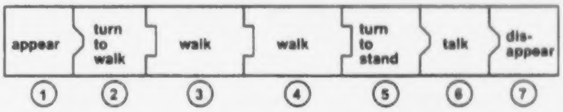

Figure 3: An example animation made from building blocks.

In order to prepare the system for a certain class of animated cartoons, one has to determine which actions the character should be able to perform. The sample actor described here should be able to 'walk', to 'stand', and to 'point' somewhere. While standing or pointing it should be able to talk to the user using either balloon or digital voice output.

The minimal set of matches needed to connect the animation sequences has to be determined. To describe their correlation, the matches and sequences are mapped onto states and transitions in a state transition diagram, cf. [Figure 4].

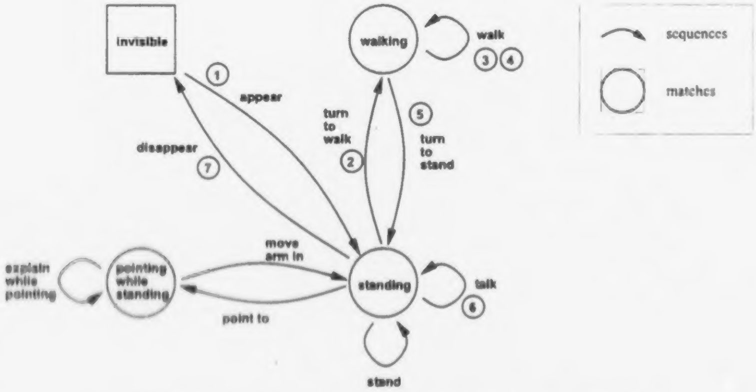

Figure 4: State transition diagram for animation example.

This example is modeled by three states (plus the 'invisible' state) for the following reasons: Every state in this diagram is equivalent to a match between building blocks (animation sequences). It is useful to keep the set of matches small, in order to keep more degrees of freedom for the composition of the building blocks, cf. [caSE: A Generic Comic Actor Sequence Editor]. Building blocks are represented by edges in the graph. The set of edges has to yield a strongly connected directed graph [Manber 89]. Given this condition, every constructable animation can be represented as a path in this graph (cf. numbers in [Figure 3] and [Figure 4]).

Every different comic actor is characterized not only by its animation sequences but also by his individual state transition diagram. A comic actor "bird", e.g., would have a quite different state transition diagram than our "dumpling" example.

4 caSE: A Generic Comic Actor Sequence Editor

4.1 Animation Sequences

Once an artist has completed the design of the generic sequences (building blocks), he must specify the matches (represented by a state in the diagram). Each match has to be named. After specifing the matches used, the sequences are introduced into the editor caSE.

For each sequence a set of properties is required: *A unique name*, the *directory path to the animation data-files*, the *matches* (Which states does the sequences' transition in the state transition diagram connect?), the *length* of

BEST COPY AVAILABLE

the sequence (frame rate and tolerance), the *default distance* (shifting over the screen) the sequence was designed for, the *movability* (Is the sequence to be played on a fixed position or can it be moved over the screen?), the *angular range* in which it can be moved (e.g., 'walk right' [-45°, 45°]), the *position of the character* in the sequence, and the *position of the hot spot* (e.g., for pointing).

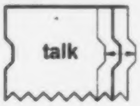

Figure 5: Tolerance in frame rate: adjustable length of sequences.

This information makes it possible to use graph algorithms [Manber 89] to cope with emerging problems: It can be checked if there are enough sequences introduced to cover the given states, by verifying the strong connection of the resulting directed graph. In addition the editor can find missing sequences if the user requests to add a sequence that is not linked with the current match. This can be done by searching the shortest path to the start transition of the requested sequence.
Example: The actor is 'talk'ing. The user wants the actor to walk. Now the editor can detect that the sequence 'turn to walk' is missing and insert it into the animation.

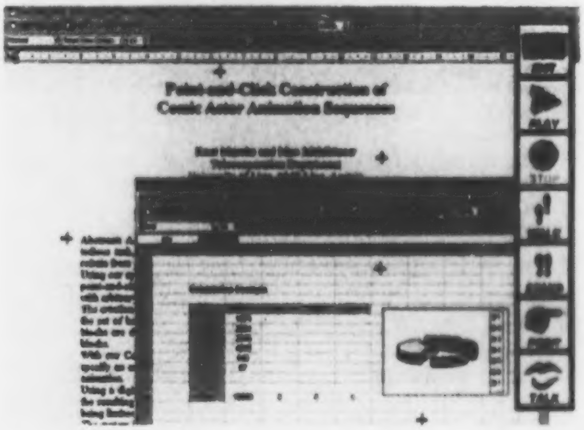

Figure 6: On-screen editor - the animation follows cross marks

We have already built a specialized editor prototype, and are working on a generic one by using the approach described in this paper. Our specialized editor implements all actions shown in [Figure 4]. It offers four actions: 'stand', 'walk', 'talk', and 'point'. Missing sequences are inserted automatically without requiring user input. All positions needed are marked directly on the desktop, where a simple cross indicates the position, cf. [Figure 6].
Additional input can be given via a popup window: For every sequence an accompanying bitmap (e.g., a balloon with prepared text) and the position of this bitmap relative to the sequence can be specified. Audio sequences can be included using WAV-files; these are played asynchronously from the beginning of the sequence. Cf. [Audio Sequences] for further discussion of this problem.
The editor saves a text file which contains all the data needed by the playing engine described below to perform the animation directly on the graphical user interface. The playing engine can be invoked and stopped directly from the editor.

4.2 Audio Sequences

Audio sequences cannot be adjusted in speed or length. For this reason it might be necessary to adjust the corresponding animation sequences in their length or frame rate.

BEST COPY AVAILABLE

Concerning the tolerance in the playing time of one animation sequence, the following considerations have to be made: The longer the audio part, the better it fits to its animation sequence because the animation sequences are relatively short and have to be repeated for a longer duration. At a certain number of repetitions n the tolerance of the used animation sequence t results in a tolerance of $n*t$ for all repetitions together. Otherwise the animation sequence has to be cut off or may have a (short) period without audio. This can be decided by the user.

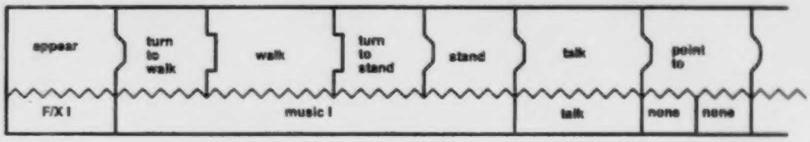

Figure 7: Combination of audio and video blocks.

5 caPE: The Comic Actor Playing Engine

5.1 Preparing the Sequences

To specify the transparent portions of the sequences, we built a tool which leverages off Apple's QuickTime technology [Apple 94], cf. [Figure 8]. Keying colours are selected by marking rectangular regions of any frame in a sequence. Every colour found inside this region will be transparent for the whole frame, in every frame of the sequence. This tool then saves the sequence in an internal file format which we custom-designed for performance reasons.

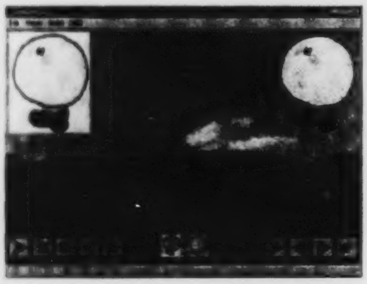

Figure 8: BlueMotion, a tool for specifying transparent portions of sequences.

5.2 On-Screen Chroma Keying

The playing engine displays the animation on the graphical user interface. It is currently implemented for MS Windows NT. The animation sequences belonging to the animation (described by an input text file generated by the caSE editor) are displayed directly on the desktop.

The engine can be used as a command-line executable or as a DLL version. The DLL version is always interruptable by the calling program and will be enhanced by a messaging concept to have more synchronization capabilities. At the end of every sequence an `END-OF-SEQUENCE` message is sent to the calling application.

The command line version is useful to integrate the comic actor functionality with standard multimedia authoring tools, e.g., Multimedia Toolbook, Macromedia Director, or even standard applications like MS Word or MS Excel.

We also experimented with sending mouse messages, e.g., to make the actor press buttons. However, the problem is that the runtime position of buttons cannot be predicted or found out for arbitrary applications: The IDs of buttons are assigned at runtime, and names of buttons are not unique. Nevertheless this feature can be used in customized applications or if a button will not change its position. A counterexample for buttons on fixed positions are the moving and vanishing toolbars of most MS Windows applications.

BEST COPY AVAILABLE

Up to now, our actor has to run on top of all other applications and still has some problems when the underlaying windows are updated during animation. We are working on this synchronization problem. By using a standard Pentium PC (133 MHz) we obtain 20 frames per second using sequences of size 320x240.

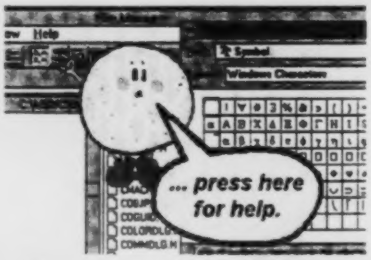

Figure 9: On-screen chroma keying.

6 Summary and Future Work

A version of our editor was shown as exhibit in the Ars Electronica Center, Linz, Austria. There it is also used as tool for courseware authoring in the "Conference/Classroom of the Future" (CCF) [Mühlhäuser et al. 96]. The animations created with our editor are used to explain the technical and pedagogical content of the CCF. The intuitive handling of the editor pleased many users. Quite often, a more generic tool where own animation sequences can be introduced was desired. Our playing engine, we are still working on, does the on-screen chroma keying with excellent performance and imperceptible cuts (matches) between different animation sequences.

In the near future, we intend to finish the generic comic actor sequence editor by using the approach described in [caSE: A Generic Comic Actor Sequence Editor]. This editor should also be able to control more than one sequence, e.g., two actors that interact with each other.

Apart from that, we are working on interaction of the actors with the user interface. Not only by pressing keys or by opening windows, but also by pushing windows away or pulling windows onto the desktop, the integration of actors with the user interface will increase.

Abstract

This paper discusses the construction of online World Wide Web based courseware within an educationally sound framework. Two courses are used as illustration, parallel computing and C programming.

1 Introduction

In recent years much attention has been paid to the delivery of teaching material over the World Wide Web. A variety of approaches have been adopted ranging from the provision of on-line lecture notes, exercises and their solutions to more interactive teaching packages. Also the intended method of use has ranged from lecture support to self-study packages.

The Dept. of Computer Science, University of Cardiff has been active in this field for a number of years and has developed courseware of varying degrees of support for a number of courses.

This paper will address the issues of implementing courseware two of its more *mature* lecture courses and details their use in a class environment. Throughout the whole of the courseware design and development we have paid close attention the educational effectiveness of the design model and presentation of the courseware. In particular this paper addresses issues of how best to provide information in such a hypertext based system and how interactive packages can be developed.

2 Module Development Strategy

Developing courseware is not merely a matter of preparing a series of lectures, linking them together and packaging them as a course. A comprehensive design strategy must also consider how to implement and manage a course, how to evaluate the materials that are used, and how to assess the learners. With that in mind, there was a conscious effort to take a systematic approach to the development of course materials. According to Rowntree [Row82] the systems approach should incorporate four basic stages: *(a)* Identify course aims and objectives; *(b)* Develop necessary learning experiences; *(c)*Evaluate the effectiveness of learning experiences; and *(d)* Improve the experiences in the light of evaluation

2.1 Stage 1: Identify Course Aims and Objectives

2.1.1 Flexibility of materials

One of the initial, intended goals of our courseware was that it can be used in a variety of courses, perhaps including undergraduate degree programmes in computer science, physics, all branches of engineering, mathematics and electronics, as well as the basis of training courses run by computer service departments. The challenge of designing learning materials for such a diverse group is to make the materials approachable for all classes of user, and yet maintain a high degree of specialism, for example, relevant to the field of parallel computing or computer vision.

Designing such materials confronts many well-established and accepted instructional design principles. The first step in many instructional design models is to analyse the learners who will use the materials. Analysis of even a subset of potential users, however, would have proved expensive and time-consuming. Therefore a compromise was made by putting effort into ensuring that the material would appeal to a broad audience.

2.1.2 The Use of Hypermedia and the World Wide Web (WWW)

There can be little doubt that the WWW has become the most successful networked multimedia hypertext based system in recent years. The *HTML* language[Cla94, Hug94] used in WWW documents is extremely simple and yet powerful to use[HMMSS94, HS94, Mar94, Mar95, MHMS+94]. These factors highly influenced our choice of hypermedia implementation systems.

However several severe restrictions in the current WWW protocol mean that more advanced *hypermedia* systems need developing.

2.2 Stage 2: Develop Necessary Learning Experiences

The materials originally designed at Cardiff were based on lecture notes from existing courses. The use of lecture materials is a logical foundation on which to build a course. On their own, however, lecture notes are insufficient. User activities during learning are more important in determining what is learned than the presentation of instructional material [MK93]. The aim of evaluating the original lecture notes was to convert them into more effective learning materials. To accomplish this, the initial lecture notes in HTML format were evaluated using models developed from principles of instructional theory. Evaluation was undertaken at an organisational level and instructional level. The organisational level focuses on courseware structure, by means of analysis of users and evaluation of the learning that has taken place. At the instructional level evaluation was concerned with the educational effectiveness of unit content.

Organisational Unit Design

We initially considered several Instructional Design models and eventually adopted an established instructional design model: the ASSURE Model developed by Heinich, Molinda and Russels[HMR93]:

A Analyse Learners
S State Objectives
S Select Media and Materials
U Utilise Media and Materials
R Require Learner Participation
E Evaluate and Revise

The use of the ASSURE model for initial evaluation allows for the systematic alteration of existing course material (lecture notes, *etc.*) by focusing on learning issues which might not have been addressed in the original lecture notes, such as the potentially diverse characteristics and experiences of users. For example, this led in many cases to the alteration of language to suit a more general audience.

Instructional Unit Design

The model described above is based on an iterative approach whereby the courseware developed is assessed and then revised. This may need to occur at the course unit level. The instructional level of evaluation is concerned with increasing the educational potential of each unit. This evaluation framework was adapted from Gagné's sequence of Instructional Events [GBW92], which are based on the hypothesised sequence of internal stages of information processing derived from studies of cognitive processes.

Utilisation of the ASSURE model and Gagné's Instructional Events is not intended to provide a prescriptive design model. Rather, it provides a framework based on sound instructional strategies within which it is possible for individual course designers to develop a dialogue about design strategies. The tools provide a common ground for collaboration. To illustrate the function of these tools in the development of educationally sound courseware, the implementation of each of the steps of the ASSURE Model will be discussed.

2.2.1 Analyse learners

As previously mentioned, it is expected that the users of the courseware will vary considerably in background and also in their purpose for using the courseware. This presents a problem in designing the courseware at the correct level of complexity, scope, *etc.* One factor affecting the model design is the anticipated implementation of the courseware. Will it be used independently of any lecturing, or in conjunction with lecturing courses, or even merely as a revision tool to support full lecturing courses? These are questions that cannot be fully answered at present, though it is probable that the courseware will be used in a variety of scenarios. It must be flexible enough to meet the various demands of the different implementations.

After evaluating the uses of the courseware it may be necessary to develop separate modules adapted to meet the various teaching environments, but which cover the same topics. At present, the courseware has been developed so as to be robust enough to stand as an independent teaching tool, with the aim that it will satisfy most of the demands made upon it. Lecturers may then be selective about the courseware material they use in their courses, adapting their courses as necessary.

2.2.2 State Objectives

Following on the assumption that the user is unfamiliar with the subjects presented, it is important that objectives are stated explicitly at appropriate levels of the courseware. This is done because the purposes of the courseware should be explained. This explanation should be part of the courseware design, particularly if it is to be used independently of lecturing.

Learners are informed specifically of what they should learn from the courseware. This approach increases their awareness of the key points in the notes, and hence increases the potential of the courseware to deliver the education required. Although each unit is prefaced by an introduction, the stating of objectives also serves as an advanced study organiser.

According to the model specification, a unit contains a list of objectives which relate to the unit as a whole, yet which can still be defined specifically. Each sub-topic within a unit also has a list of objectives which cover that particular sub-topic. Thus the stating of objectives reflects the hierarchical design of the model.

2.2.3 Select Media and Materials

The decision to use the WWW (and subsequent WWW browsers) as the medium for delivering the courseware was made at the commencement of the project. Consequently, the selection of media and materials has been less restrictive than conventional choices, due to the diversity of media formats supported by WWW browsers.

2.2.4 Utilise Media and Materials

The following mechanisms have been used in the development process: *(a)* Using MPEG Movies to Animate Algorithms; *(b)* Using Forms and Scripts to Achieve User Interaction; and *(c)* Using Java for true algorithm animation and user interaction.

2.2.5 Require Learner Participation

Hypermedia has been described as a more active learning medium than text because it forces learners to make decisions about which links to follow. This has been described by Romiszowski [Rom94] as a feed forward system: the user has control over which information nodes to view or ignore. This is a restricted form of interaction, however, which neither indicates nor ensures that the learner is processing the material at a deep cognitive level.

Each unit therefore includes exercises developed specifically to examine a range of learning objectives, from the testing of simple verbal knowledge, to more complex problem solving.

2.2.6 Evaluate and Revise

This step of the ASSURE Model is concerned with the evaluation and revision of the courseware to meet the constraints imposed by the implementation environment.

703

2.3 Stage 3: Evaluate the Effectiveness of Learning

One of our concerns was how to evaluate the teaching materials. A traditional approach is to look at both the product - the materials that have been produced - and the procedure, *i.e.* how students learn from the material. The evaluation should seek to answer how well the objectives of instruction have been met, and what effects the use of the materials had on the learners. Such an evaluation is necessarily influenced by the way that the materials are implemented, so any evaluation of the materials must necessarily wait for field trials. What has been attempted is to develop general evaluation tools which will be included in each unit. They aim to address both organisational and instructional levels. One advantage of using HTML for this purpose is that it is possible to link evaluation forms to each module. The forms include Likert scales and spaces for comments.

To evaluate the effectiveness of the teaching materials, learners will be asked to rank their confidence for understanding a particular learning objective. Each learning objective for the unit will be stated, and confidence ranked accordingly. The feedback received from this data will allow designers to evaluate the effectiveness of the material at the level of the individual unit.

2.4 Stage 4: Improve the experiences in the light of evaluation

Improvement of the learning materials will depend partly on how they are implemented. Each of the scenarios that have been mentioned are potentially useful both educationally and financially. Undoubtedly, the material will need to be altered and adapted to suit the needs of particular students and subject domains. The evaluation tools that will be included with each unit will provide users of the material with some of the feedback needed to improve the experiences of learners. A detailed evaluation of the material, however, is possible only once the materials are in use and detailed field studies can be undertaken.

3 Parallel Computing Courseware

The material produced was developed with the aim of aiding the teaching of high performance computing throughout the university sector in the UK. The course consists of four *books*:

1. *A Classification Scheme for Parallel Computers.* This book describes Flynn's classification scheme for parallel computers.
2. *Interprocessor Communications.* This book describes two methods by individual processors within a parallel computer can send messages to other processors within the same machine.
3. *Load Balancing and Task Scheduling.* This book describes two methods by which an algorithm written for a parallel computer can achieve high efficiency by ensuring that all the processors are performing equal amounts of work.
4. *Parallel Algorithms.* This book describes the writing of algorithms for parallel computers.

To describe the essential features of the parallel computing courseware we will describe the book on Interprocessor Communications. Initially, after selecting this section from the four books mentioned above the user is presented with the page given in Figure 1.

This page (Figure 1) provides the following high-level information to the user:

- The top left area of the page outlines the contents of the book. This provides information not only on the titles of the book's chapters but also provides a means of directly accessing the chapters of interest (by clicking on its title) e.g. clicking on *Shared Memory* takes the user directly to this section in the book. The contents list also indicates the current position of the user in the book.
- In the bottom left part of the page, navigational aids are provided *(i)* to move around the information contained in particular books and *(ii)* to allow movement between different books. The various options are illustrated in Figure 2
- The right part of the page usually contains three subsections:
  - At the top the *Outline* section presents a very general and brief description of the topic under consideration, i.e. in this case interprocessor communication. The purpose of this is to allow the user to decide quickly whether the correct page has been accessed.

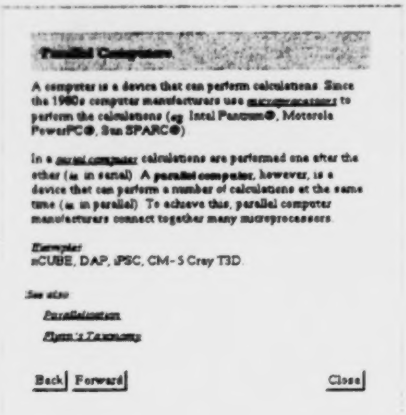
BEST COPY AVAILABLE

- The main part is the *Course* section. This gives a more detailed description of interprocessor communication (or whatever topic is under investigation) and includes links to relevant new topics such as Shared Memory and Interconnection Networks.

  Highlighted keywords in italics (and underlined), are links to background information which the user may need reminding of. For example, clicking on *parallel computing* gives a brief definition of parallel computing and is illustrated in Figure 3.



Parallel Computers

A computer is a device that can perform calculations. Since the 1980s computer manufacturers use microprocessors to perform the calculations (eg Intel Pentium®, Motorola PowerPC®, Sun SPARC®)

In a serial computer calculations are performed one after the other (ie in serial). A parallel computer, however, is a device that can perform a number of calculations at the same time (ie in parallel). To achieve this, parallel computer manufacturers connect together many microprocessors.

Examples:
nCUBE, DAP, iPSC, CM-5 Cray T3D

See also:
Parallelisation
Flynn's Taxonomy

Figure 3: Background Information: Parallel Computing

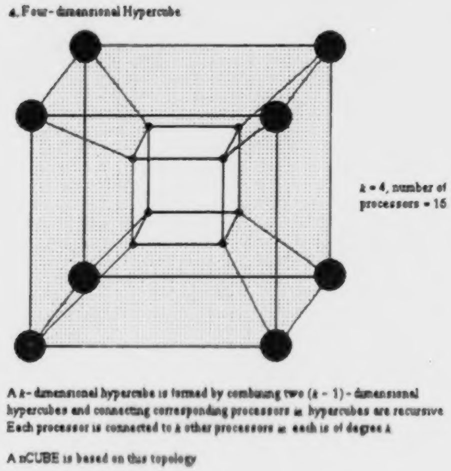
  Highlighted keywords or phrases that are not in italics are links to detailed information on the concepts under consideration, e.g. selecting *Interconnection Networks* would present the user with detailed information on their description, give examples, show mpeg movies etc. (e.g. Figure 4).
- The *Further Reading* section provides details of reference books (or articles), with page numbers, so that additional information can be obtained on the topic under consideration.

Overall, the courseware has been developed and constructed such that the user (i.e. student) is provided with concise relevant information and is not overwhelmed with too much detail per page. Navigational aids are constructed so that the students can search the complete course and individual books relatively easily. The general principles used in developing the parallel computing courseware can be applied to any subject areas.

4 C Programming

The basic design methodology of Section 2 has been extended in the following way for the C programming courseware [CM96, Mar95, MH96a, MH96b, MH96c, MHMS⁺94]:

- A form based key word search CGI was implemented.
- At the end of each chapter an exercises section was provided which adhered to the provision of exercises in the lecture course.
- Links for each exercise were provided to the Ceilidh automatic program marking systems ([ZF91]) to provide to the following :
  - Model solutions to exercises.
  - Interface to Ceilidh's automatic program marking module (Fig. 5).
- Links so that listings of programs can be obtained at relevant points in the notes.
- Interactive Java Applets to illustrate key data structure concepts (*e.g.* Linked Lists and Trees) have been implemented (Fig. 6).
- Links to alternative notes around the WWW.
- Links to local on-line information about using the workstation, C compilers, UNIX programming and on-line manuals.



a. Four-dimensional Hypercube
$k = 4$, number of processors = 16

A k-dimensional hypercube is formed by combining two $(k - 1)$-dimensional hypercubes and connecting corresponding processors ∴ hypercubes are recursive Each processor is connected to k other processors ∴ each is of degree k

A nCUBE is based on this topology

Interaction by Electronic Mail in University Studies

Miika Marttunen
University of Jyväskylä
Department of Education
Finland
E-mail: mmarttun@campus.jyu.fi

Abstract: A university course in which 31 undergraduate students practised academic argumentation in an e-mail study environment is described. In the two tutor-led 'e-mail study groups' the discussion themes were selected by the tutor while in the two student-led 'discussion groups' by the students.

The quantity and quality of student-student interaction was analysed. The results indicated that 42 % of the messages were interactive in nature including at least one reference to fellow students' messages. When difficult contents were addressed the tutor's guidance was found to be important in producing student interaction. From all the references (n = 259). 62 % expressed something else than taking of an attitude. 24 % agreement. 10 % grounded disagreement. and 4 % non-grounded disagreement. Grounded disagreement with fellow students turned out to be more common in the student-led groups while the students in the tutor-led groups expressed more often agreement.

Introduction

There is an increasing number of accounts of the use of electronic mail [e-mail] in elementary and secondary levels of education [Wells. 1993]. as well as in academic environments in which its appropriateness is widely recognized [Thomas. 1994]. The central reason for this is that the use of e-mail facilitates and increases interaction between participants and provides them with a collaborative learning environment. The positive learning effects of collaborative e-mail interaction have also been reported in several studies [for example Burge. 1994].

Characteristic of academic interaction is its argumentative nature. People possessing mature argumentation skills are able to present relevant and sufficient reasons for supporting their claims [Voss & Means. 1991; Marttunen. 1994] as well as to assess the strengths and weaknesses of different approaches and to present counterarguments. Perry [1981] emphasizes that argumentation plays a central role in developed scientific thinking since it includes the skill to provide evidence in support of one's opinions. Scientific thinking presupposes also a critical attitude towards knowledge. According to Byrne and Johnstone [1987], a critical attitude includes factors common with argumentation skills. such as objectivity. caution in drawing conclusions and weighting evidence. Hence. practising of argumentation can be regarded as essential in promoting the key objective of university teaching: teaching students the tools needed in scientific thinking.

To engage in interaction with other people has been found to be a successful way to practise argumentation and critical thinking [Smith. 1977]. Engaging in counterargumentation and debate has been especially emphasized as modes of interaction that promote students' learning of argumentation [Littlefield. 1995]. Since e-mail environments have been claimed to be appropriate in establishing interaction especially between students [Ruberg. Moore & Taylor. 1996] e-mail has been used in teaching informal argumentation and critical thinking [Charlton. 1993; Marttunen. in pressa. in pressb].

E-mail interaction has been previously studied by focusing on its amount [Ruberg. Moore & Taylor. 1996]. structure and contents [Friedman & McCullough. 1992]. and the interactive elements of e-mail messages [Henri. 1992]. However. students' cognitive processes during e-mail discussions have been studied much more seldom. although some such studies are available. The recent studies by Newman. Webb and Cochrane [1995] and Newman et al. [1996] revealed a deeper overall critical thinking ratio in the e-mail discussions compared to face-to-face discussions. In another study Ahern. Peck and Laycock [1992: see also Marttunen in pressb] found that in such an e-mail environment in which the students had more freedom to present their standpoints, most student-student interaction and argumentative discourse took place.

This study builds on these previous investigations on e-mail interaction by focusing on the quality and quantity of student-student interaction during a university course organized by e-mail. The questions addressed are: 1) How much student-student interaction did the students' e-mail messages include? 2) How argumentative was this interaction? 3) What kind of factors were associated with the quality and quantity of interaction?

Method

Subjects

The e-mail studies were carried out in connection of a M.Ed level introductory course in the sociology of education at the Department of Education at the University of Jyväskylä, Finland, during the autumn term 1990. The participants, 31 undergraduate students, were recruited to the experiment on a voluntary basis.

E-mail Study Arrangements

The studies were organized by using university's mainframe computer (Sun) and its electronic mail program (Elm) equipped with the text editor Emacs. A distribution list was attached to the e-mail system which made many-to-many communication between the students possible. The students could operate e-mail by using the terminals and personal computers located on-campus, or at home if they had a computer and a modem available.

Four e-mail study groups were established: two parallel groups engaged in the seminar mode and two parallel groups in the discussion mode of the e-mail study. Two top students near their graduation were also recruited as tutors to the studies. In the *seminar groups* the tutor selected the discussion topics and gave the students regular feedback. His role was to act as a teacher and a chairman of studies. In the *discussion groups*, by contrast, the students were allowed to select the discussion topics by themselves while the tutor acted, rather, as a co-learner and a facilitator of learning for the students.

During the six week e-mail studies the students were supposed to send from two to three messages a week in order to pass the course. Within each individual study group the messages were automatically delivered to all the group members and to the tutor through the distribution list.

In their e-mail messages the students were supposed to deal with the contents of the set books (Donald Broady: The Hidden Curriculum; Tuomas Takala (Ed.): Basics of Educational Sociology) and course lectures. Since the content of Broady's book was conceptually complicated and touched only slightly the students' life experiences it was classified as '*difficult*'. By contrast, since Takala's book delt with a wide range of such themes (e.g. 'gender and school', 'youth cultures', 'economy of education', 'social mobility') that the students were familiar with on the basis of their previous life experiences it was classified as '*easy*'. In the discussions the students practised argumentation by presenting in their texts their own grounded opinions on issues included in the course contents. The students were especially encouraged to engage in counterargumentation by presenting grounded critique towards the other students' arguments and by defending their own arguments when critiqued by others.

Data

The students wrote 489 e-mail messages during their studies. From these the messages relevant in terms of the study of the course contents were included in the data ($n = 441$). The 48 excluded messages dealt solely with technical matters and organization of the e-mail studies.

Interaction Analysis

The analyses of the students' messages concentrated on explicit student-student interaction by defining the references pointing to fellow students' messages sent earlier [see Henri, 1992]. The analyses proceeded through two phases. In *the first phase* the students' messages were classified into interactive and non-interactive messages (X1). An interactive message included at least one reference to a message sent by a fellow student earlier, and a non-interactive message did not include any such references. In addition, the messages that included responses to responses were defined as real-interactive messages [see Bretz, 1983], and the messages that did not include such references as non real-interactive messages. *The second phase* of the analysis concentrated on the nature of the references by classifying them into four categories: a) agreement, b) grounded disagreement, c) non-grounded disagreement, or d) non-relevant. The references expressing *'agreement'* indicated that the writer shared the opinion with the fellow student, while the references expressing disagreement indicated that the student was of the opposite opinion, either totally or partially, with the fellow student. The references in which the writer had grounded his/her disagreement were classified into the category *'grounded disagreement'*, and the references in which the counter-opinion was not supported with grounds to the category *'non-grounded disagreement'*. The content of the references classified into the category *'non-relevant'* was not relevant in terms of counterargumentation expressing something else than taking of an attitude. Such references expressed, for example, questions, answers to questions or appeals etc.

Statistical Analyses

Logit-models [Goodman, 1979] were used in determining factors associated with the quality and quantity of interaction in the messages. Five separate Logit-analyses were carried out. The dependent variable varied in the different analyses while the independent variables were the same. Each of the dependent variables divided the messages into two categories on the basis whether the property in question appeared (value 1) in the message or not (value 0). The dependent variables were '*Interactivity of the message*' (X1), '*Occurrence of references indicating agreement*' (X2), '*Occurrence of references indicating grounded disagreement*' (X3), '*Occurrence of references indicating non-grounded disagreement*' (X4), and '*Occurrence of non-relevant references*' (X5). The Independent variables were '*Mode of the e-mail study*' (X6, tutor-led vs student-led), '*Gender*' (X7, male vs female), and '*Book*' (X8, difficult vs easy).

The analyses indicated that the independent variable 'Mode of the e-mail study' (X6) had a statistically significant main effect with the dependent variables 'Agreement' (X2) and 'Grounded disagreement' (X3). In addition, variables 'Mode of the e-mail study' (X6) and 'Book' (X8) had a statistically significant interaction effect with the dependent variables' Interactivity' (X1) and 'Non-relevant' (X5). The independent variables 'Mode of the e-mail study' (X6) and 'Gender' (X7) had, as well, a statistically significant interaction effect with the variable 'Interactivity' (X1) while none of the independent variables employed in the analyses was associated with the dependent variable 'Non-grounded disagreement' (X4).

Results

Quantity of the E-mail Interaction

According to the results, 42 % of the messages were interactive in nature including at least one reference to a message sent by a fellow student earlier. In addition, 6 % of all the messages included real interaction [Bretz, 1983] indicating that a student had responded back to a fellow student's response to his/her original statement.

Furthermore, although the amount of interactive messages was quite low, the results showed that all of the e-mail students (n = 31) engaged in interaction: two (6 %) of the students referred twice to a fellow student's message, seven (23 %) three times, and 22 (71 %) four times or more.

The results of the Logit-analyses indicated that the variables 'Mode of the e-mail study' (X6), 'Gender' (X7), and 'Book' (X8) affected the interactivity of the messages. Table 1 illustrates the effects of these variables.

Table 1: Differences in the interactivity of the messages by the mode of the e-mail study

	Mode of the e-mail study					
	Seminar		Discussion		Total	
Interactivity of the message	f	(%)	f	(%)	f	(%)
Messages concerning difficult contents (Broady's book, n = 150)						
Interactive	44	(52)	16	(24)	60	(40)
Non-interactive	40	(48)	50	(76)	90	(60)
Total	84	(100)	66	(100)	150	(100)
Messages sent by female students (n = 204)						
Interactive	56	(49)	26	(29)	82	(46)
Non-interactive	59	(51)	63	(71)	122	(54)
Total	115	(100)	89	(100)	204	(100)

According to the results [Tab. 1], the messages concerning difficult contents were more often interactive in the seminar groups (52 %) than in the discussion groups (24 %). The results indicated also that female students sent more interactive messages in the seminar groups (49 %) than in the discussion groups (29 %).

Quality of the E-mail Interaction

The results concerning the nature of the references (n = 259) indicated that 62 % of the students' references to fellow students' messages were non-relevant in terms of argumentation expressing something else than taking of an attitude. In addition, 24 % of the references expressed agreement, 10 % grounded disagreement, and 4 % non-grounded disagreement.

The results of the Logit-analyses revealed that the variables 'Mode of the e-mail study' (X6), and 'Book' (X8) explained the appearance of different kinds of references in the students' messages. Table 2 clarifies the associations between these variables.

Table 2: Differences in the presence of different kinds of references in the student's messages by the mode of the e-mail study

	Mode of the e-mail study					
	Seminar		Discussion		Total	
Variable	f	(%)	f	(%)	f	(%)
Agreement (X2, n = 320)						
Yes	31	(17)	9	(6)	40	(12)
No	147	(83)	133	(94)	280	(88)
Total	178	(100)	142	(100)	320	(100)
Grounded disagreement (X3, n = 320)						
Yes	4	(2)	14	(10)	18	(6)
No	174	(98)	128	(90)	302	(94)
Total	178	(100)	142	(100)	320	(100)
Non-relevant (X5, n = 150)*						
Yes	31	(37)	9	(14)	40	(27)
No	53	(63)	57	(86)	110	(73)
Total	84	(100)	66	(100)	150	(100)

* Messages concerning difficult contents

The results indicated [Tab. 2] that the students in the seminar groups produced more often messages including references that indicated agreement with their fellow students than did the students in the discussion groups (17 % vs 16 %). By contrast, the students in the discussion groups sent more often messages in which they referred to their fellow students in a way that indicated grounded disagreement (10 % vs 2 %). The results indicated also that when the messages concerned difficult contents the students in the seminar groups sent more often messages that included such references to their fellow students that were not relevant in terms of argumentation (37 % vs 14 %).

Discussion

The results showed that a majority of the students' e-mail messages were non-interactive in nature. This result suggests that although the pedagogical aim of the e-mail studies was to engage the students in interaction this aim was not realized very well. However, despite the low proportion of interactive messages, all of the e-mail students did engage in interaction by referring to a fellow student's message at least twice. Thus, it can be said that the e-mail study, to a certain extent, supported the students' engagement in interaction. Similar findings have also been reported by Ruberg, Moore & Taylor, [1996] who found that the use of e-mail increased student-student interaction in particular. The results of this study are especially important in the context of Finnish higher education in which one of the major problems is the lack of student-student interaction and the scarcity of study methods based on critical discussion of issues. The results namely suggest that interaction between students in higher education studies can be created by using e-mail. Furthermore, in the light of previous study results [Zirkin & Sumler, 1995], the results in this study suggest that the use of e-mail promotes student's learning as well. In their summary of literature on studies on interaction Zirkin and Sumler report findings indicating that the more interactive the learning environment was the more favourably the instruction was perceived and the more effective the learning outcome was likely to be.

The results indicated also that the mode of the e-mail study along with the nature of the contents and gender proved factors associated with the interactivity of the messages: when the discussions were based on difficult contents (Broady's book) the tutor-led seminar mode produced more student interaction, although non-relevant in terms of argumentation, than did the student-led discussion mode. In addition, the results showed that the female students engaged in the seminar mode produced more interaction that those who were engaged in the discussion mode. These results suggest, *first*, that when the e-mail discussions are based on difficult contents the directive role of the tutor is important in order to get the students discuss matters and exchange opinions. However, when the students discuss easy contents the tutor's role seems to be less important in terms of producing interaction between students. *Second*, the results suggest that the directive role of the tutor increases the amount of interaction produced by women while men seem less prone to react to variations in the tutor's activities.

Furthermore, according to the results the interaction between the students was mainly non-argumentative in nature: only 14 % of the students' references to each others' texts expressed an opposite opinion with a fellow student. When interpreting this result it is important to take into account the study of Terenzini et al. [1995] according to which attending the intellectual atmosphere of college and university studies promotes the development of argumentation and critical thinking skills. Since most of the e-mail students in this study had only a short-term study experience the result indicating a small amount of argumentative references becomes more understandable.

The results revealed also that grounded disagreement with fellow students was more common in the discussion groups while the students in the seminar groups expressed more often agreement. This result indicates that when the students' self-directive learning was supported by providing them with the possibility to select the discussion topics by themselves, grounded counterargumentation was most likely to come about. Ahern et al. [1992] also reported findings that supported the favourability of self-directive e-mail study when aiming at producing student interaction. Hence, the study suggests that providing the students with freedom to direct their studies can be regarded as a beneficial and sensible way to organize students' working in an e-mail environment, especially when aiming at practising academic argumentation.

Abstract: The Educational Technology Laboratory at the Medical University of South Carolina (MUSC) has developed a model Internet site to demonstrate ways in which interactive instruction can be provided over the Internet. An ad hoc committee composed of volunteer faculty members provided assistance, insight, and evaluation during the development of the site. Throughout the process, the development team focused on student learning, rather than the technology of the Internet. During demonstrations of the site, the audience was encouraged to think about the same issues the development team considered during production: What do students need to learn? What are effective methods and strategies for learning? Can there be a match between what students need to learn, the methods and strategies for learning, and the capabilities of the Internet? How could use of the Internet as an instructional tool change the role of a teacher? As a result of these demonstrations, faculty members are working with the Educational Technology Laboratory to develop interactive Internet sites designed for learning.

"At the Medical University of South Carolina, the University's academic programs are designed to...emphasize the development of critical thinking abilities, encourage curiosity, and instill a desire for lifelong learning." [Owens, 1996]

"The Internet provides a new medium for reaching out to find knowledge and meaning." [Negroponte, 1995]

BEST COPY AVAILABLE

- All over the United States, vinyl records are stored away in boxes collecting dust because people recognized the advantages of the CD, including its improved sound quality and durability
- Portable phones are popular due to their compatibility with our mobile lifestyles
- Microwave ovens have been readily accepted not only for their speed but their ease of use, as well.
- A reduction in a monthly utility bill makes it easy to observe the advantages of installing the latest "high tech" double insulated windows
- Following a trial period, a large school district quickly adopted a policy that provided schools the option of requiring students to wear uniforms [Charleston County School District, 1996]

Rogers [1993] reports that an innovation is an idea, practice, or object that is perceived as new by an individual or other unit of adoption. According to this definition, CDs, microwave ovens, portable phones, insulated windows, and the concept of public school uniforms were at one time considered innovations; so is the Internet. Why are some innovations adopted while others are not? What makes the difference? Will use of the Internet as an instructional tool be seen as an innovation worthy of adoption, or will it start with a bang and quickly fade away? It is an innovation's relative advantage, compatibility, complexity, observability, and/or trialability, that are the major factors that determine its adoptability [Rogers, 1993]. Therefore, can the Internet be shown to have advantages over other instructional tools? Is it compatible with instructional methods that already exist? Is it complex to use and/or maintain? Can it be given and/or taken in "small doses" (e.g., "trial periods")? Are results of its use easy to observe?

Perhaps focusing on what it is we want students to LEARN rather than the TECHNOLOGY of the Internet will provide educators with the opportunity to recognize the instructional potential of the Internet, and that the Internet is an innovation worthy of adoption. According to Reeves [1996], the effectiveness of learning on the Internet is a function of the skills and experience learners have with it and the degree to which curricula and Internet sites have been designed to support sound pedagogical dimensions. Therefore, before exploring the use of the Internet as an instructional tool, it is important to focus on some of the key aspects of learning and effective teaching strategies, such as those outlined by Laurillard [1993]:

Apprehending Structure - Students construct meaning as they read, listen, act and reflect on the subject content. However, as Laurillard [1993] points out, "Meaning is given through structure" [p. 51], and it is therefore essential that students are able to interpret the structure of any discourse before they can construct meaning that is crucial to understanding. Students adopting a surface approach to learning would fail to do this, as they focus on memorizing a number of phrases and points or later reproduction.

Integrating Parts - Students need to be able to integrate the signs of knowledge such as language, symbols, and diagrams with what is signified by them.

Acting on the World - There are few teachers who attempt to teach without asking students to do something, whether it be laboratory sessions or essay writing. Students are asked to engage in some form of activity which, when integrated with other activities, assist in understanding of content.

Using Feedback - Actions such as those mentioned above are futile for student learning, unless feedback on individual action is available.

Reflecting on Goals-Action-Feedback - Learners interpret and understand reality as they make links between each of the above aspects by reflecting on the goals of learning, actions taken, and the results of those actions.

The challenge for educational developers is to use this knowledge of learning together with an understanding of the features of the Internet, to design learning

BEST COPY AVAILABLE

experiences which promote a deep approach to learning, so that "what" students learn is a deep understanding of the subject content, the ability to analyze and synthesize data and information, and the development of creative thinking and good communication skills [Alexander, 1995].

Many of these aspects of learning are reflected in a portion of the Medical University of South Carolina's educational philosophy:

> "At the Medical University of South Carolina, the University's academic programs are designed to ...emphasize the development of critical thinking abilities, encourage curiosity, and instill a desire for lifelong learning. Learning is viewed as an active, dynamic process for which students and faculty share responsibility...The educational experiences of all University students are designed to incorporate opportunities for interdisciplinary dialogue and collaboration in classroom, clinical, and social settings. To meet better the educational needs of our students and the health care needs of South Carolinians, clinical learning experiences occur in community-based and primary care sites, as well as the more traditional tertiary and specialty care settings." [Owens, 1996]

As the Medical University of South Carolina strives to implement this educational philosophy, it is also attempting to address the same issues faced by other institutions of higher education:

- due to students' schedules and needs, requests are being made for classes delivered over the Internet, allowing "anytime, anywhere access"
- distance education courses and degree programs are reaching students all over the country, providing competition among schools for enrollment
- on-line courses, degree programs, and the use of technology appear to be marketing strategies and without them, a school may be considered "behind the times"

In light of these factors, the Educational Technology Laboratory at the Medical University of South Carolina developed a model Internet site to demonstrate to the administration and faculty possible ways in which the Internet, when used as an instructional tool, could address some of these issues. At the same time, the Educational Technology Laboratory also recognized that providing on-line courses would require more than one or two faculty members developing several web pages. In fact, it could be argued that individual faculty members can conduct individual experiments that point the way to systemic change, but they cannot make significant, systemic changes by themselves. Higher education needs to begin with a clear vision of what it is they are trying to accomplish in the field of technology-mediated learning. Too often, discussions about the integration of technology and instruction begin with the question, "Why hasn't it worked?" This is usually followed by, "How can we get them to use it?" Technology is an enabling mechanism; it is not an end in itself.

Therefore, the first decision made in planning for the development of this model Internet site was to enlist as much support as possible on a campus-wide basis. The University Education Committee (UEC) was the logical place to garner support since it is composed of representatives from all of the colleges on campus (e.g., nursing, pharmacy, medicine, dental medicine, health professions, etc.). This committee's charge is to support the University's educational philosophy and develop guiding principles on issues such as distance education and technology-mediated learning. The proposed design of the model Internet site supported the University's educational philosophy and the UEC's goals for distance education. Therefore, the Educational Technology Laboratory approached the UEC for support of the proposed project, in turn receiving a statement of commitment and support, as well as a small grant.

The model Internet site developed by the Educational Technology Laboratory is designed to:

- assist administrators and faculty in further clarifying what the Medical University of South Carolina is trying to accomplish in the area of technology-mediated learning
- demonstrate ways in which the Internet can enable students to become the kind of learners referred to in the University's educational philosophy: critical thinkers, curious, and possessing a desire for learning

After obtaining the endorsement of the University Education Committee for development of this site, the Educational Technology Laboratory asked for faculty volunteers to form an advisory ad hoc committee. Fifteen faculty members volunteered. The purpose of this ad hoc committee was to provide a forum for discussing issues that needed to be taken into consideration through the development process (e.g., design issues, instructional needs, student connectivity, and administrative needs). The ad hoc committee's suggestions were incorporated throughout the process. Their participation also provided an initial basis of support for this project among the administration and faculty.

The model Internet site is divided into three areas: resources, communication, and content. These three areas are integrated into a single HTML page with all of the features of the program accessed from one page (e.g., e-mail, chat lines, video conferencing, etc.). The resources section provides access to assignments, a class syllabus, and a link to the library's databases. These resources assist students in understanding the structure of the course content so that a base of information is provided upon which to build comprehension and understanding. In order to demonstrate ease of use, a password secure area allows a faculty member to update or change assignments from their own computer. The communication section provides an opportunity for students and faculty to easily send, receive, and check e-mail, join class list serves, and participate in live "chat" sessions or video conferences. Through increased access to faculty, useful resources can be shared and problems solved jointly. In addition, these communication technologies allow students and faculty to exchange work more thoughtfully and "safely" than when confronting each other in a class or faculty office. The model site also illustrates possible uses of interactivity over the Internet. For example, students can label a medical illustration and complete an evaluation receiving immediate feedback, including a score and the correct answers. Students also have the opportunity to share their ideas and respond to others through group discussion questions related to the "real world". Chickering and Ehrmann [1996] state that sharing ideas and responding to others' improves thinking and deepens understanding; students must also talk about what they are learning, write reflectively about it, relate it to past experiences, and apply it to their daily lives. The discussion questions on the model site provide this opportunity. In addition, all of the activities and teaching strategies incorporated into the model site give students an opportunity to employ the key learning aspects identified by Laurillard [1993]: apprehending structure, integrating parts, acting on the world, using feedback, and reflecting on goals-action-feedback.

Demonstrations of the Internet site have been made to faculty and administrators, first emphasizing the use of the Internet as an instructional tool. Secondly, these demonstrations have addressed instruction over the Internet as an innovation and how characteristics of an innovation may encourage adoption: its advantages over other forms of instructional tools, its compatibility with current instruction, lifestyles and student needs, its lack of complexity and opportunities for trialability [Rogers, 1993]. In each demonstration, the audience was encouraged to think about what they wanted students to learn and whether or not the appropriate instructional methods and strategies could be provided over the Internet. Demonstrations also provided examples of ways in which course delivery over the Internet could influence teaching styles, thereby providing greater opportunities to change from a lecturer to a mentor and guide. Other issues discussed during demonstrations included student acceptance of instruction over the Internet, and the "nuts and bolts" that needed to be taken into consideration prior to the development of an on-line course.

As a result of this model site, the Educational Technology Laboratory is working with various faculty members in the design and production of courses or portions of courses that will be delivered over the Internet. The Educational Technology Laboratory believes that the Internet can be considered a new media teaching tool. Internet developers can benefit from the wealth of related research, the way people learn the strategies that promote the kind of learning we value, and the lessons learned by earlier technology developers. If we use this knowledge, students of today can look forward to ever increasing ways in which this technology can assist them in becoming lifelong learners.

Necessary Ingredients of Integrated Network Based Learning Environments

Hermann Maurer, Graz University of Technology/Austria
hmaurer@iicm.edu http://www.iicm.edu/maurer

Abstract: In this paper we present for the first time to a wide public the MANKIND project: MANKIND is an acronym for *M*ultimedia *A*nd *N*etworked *K*nowledge-transfer *I*ntroduces *N*ew *D*imensions. It is an ambitious undertaking that combines know-how obtained through extensive research and efforts in network based training and education with work on digital libraries and the development of the advanced WWW server system Hyperwave (formerly called Hyper-G).

It is our belief that CAI (Computer Assisted Instruction), CBT (Computer Based Training), ITS (Intelligent Tutoring Systems), WBT (Web Based Training) and similar efforts that have tried to support teaching and learning through (networked) computers have generally failed and will continue to do so, unless an integrated approach is taken, i.e. unless all necessary ingredients are taken care of. The MANKIND project is probably one of the first such integrated efforts. Parts of it are operational and indeed in use (e.g. for distributed training for MOTOROLA employees world-wide, as teaching support at the Graz University of Technology or at Queens University [Skillicorn 1996], or as teaching and lecturing support system at the University of Freiburg [Bacher et al 1996]); other parts are under development and yet others still in the planning stage. This paper is a summary of the main points that are being tackled by MANKIND. Any other system, existing, under implementation or being planned should be measured by how well it matches the „ten guidelines for MANKIND" outlined in the main section 2 of this paper.

1. Introduction

The history of efforts to use computers for educational purposes is over 35 years old and is (overall) a history of failures. An analysis why this is so, and why - nevertheless - new waves of efforts have started every few years (and we are witnessing another Web-based wave right now) is contained in chapter 1 of [Maurer et al 1996] and will not be repeated here.

Let it be sufficient to say that all attempts, so far, have had serious deficiencies one way of another. Some of them due to technical reasons, some due to the lack of pedagogical theories, most of them through a combination of both and the fact that no system has provided enough flexibility. None has provided a rich enough variety of learning and teaching models allowing it to be tailored towards specific subject areas and particularly towards individual student knowledge acquisition techniques.

The MANKIND project it not trying to follow a particular cognitive paradigm. Rather, it tries to provide facilities that allow the incorporation of very diverse models of knowledge-transfer. Its success will be measured by how flexible educators and students will find the system for the adoption to their needs.

The main section of this paper, section 2, contains the „Ten guidelines for MANKIND" that we consider necessary ingredients of any integrated network based learning environment. The aim of the MANKIND project is to create an environment satisfying the ten guidelines; it is based on the currently most advanced WWW server system Hyperwave (see e.g. http://www.hyperwave.com and references mentioned later). The

BEST COPY AVAILABLE

guidelines have been derived from much research and concrete experiments starting with COSTOC (e.g. [Makedon et al 1987], [Huber et al 1987], [Huber et al 1989], [Gillard et al 1990], [Maurer et al 1990], to HM-Card (e.g. [Maurer et al 1995a], [Maurer et al 1996], from work in digital libraries (e.g. [Maurer et al 1994], [Marchionini 1995], [Maurer et al 1995 b], [Lennon et al 1995a]) to the development of the advanced WWW - server systems Hyperwave (formerly Hyper-G) e.g. [Kappe et al 1993], [Kappe et al 1994], [Fenn et al 1994], [Andrews et al 1995a], [Andrews et al 1995b], [Andrews et al 1995c], [Maurer 1996a], and taking into account recent related work such as [Mühlhäuser 1995], [Adam et al 1995], etc.

In section 3 we will review which of the guidelines to be described have already been implemented based on Hyperwave and what the situation is like concerning the remaining ones.

2. The ten guidelines for MANKIND

In this section we present ten general theses (guidelines) that must be kept in mind when designing or evaluating an integrated teaching and learning environment. Some of them have already been analysed in more detail in LATE (see [Maurer 1996b]) which provides goo background reading. Note that the ten theses presented are also seen as the basic guidelines for project MANKIND mentioned earlier.

Thesis 1: No matter what technology is used, insights obtained for traditional courseware design both from a pedagogical and content/form point of view must not be ignored.
It is amazing to see that in current multimedia efforts based on HTML (WWW) pages, HyperCard or Macromedia derivatives and the like many of the lessons learnt (see e.g. [Kearsley 1982], [Nievergelt 1980]) on courseware design are completely neglected. Too many persons seem to believe that linking a few HTML pages together produces viable material for teaching and/or learning purposes. Whenever a substantial piece of courseware is designed it is e.g. essential that aims and prerequisites are clearly stated, that the material is well motivated, that features technically available like fonts, colour, graphics, animations, etc. are not used as gadgetry but only when helping to understand the issues to be communicated; that student interaction beyond „electronic page turning" is essential and can often be achieved using checkpoints with feedback, built-in simulation, guided tours of material presented in one window, a second window used for guidance; that the level of the material is sufficiently concrete (e.g. through the use of examples); that the tone is personal yet not condescending, etc., etc. We refer to the literature mentioned, including chapter 6 of [Maurer 1996] for more details. However, we want to point out that most technologies allowing the creation of courseware permit the creation of both well-done and unsuitable material. They usually do not provide „built-in guidance" to avoid at least some of the most glaring pitfalls. We consider this an important area of work, yet an area not directly addressed in MANKIND that (see below) takes an open view as far as „authoring tools" are concerned.

Thesis 2: The production of high-quality courseware has to be made as easy as possible.
In a system like MANKIND this means basically four things. First, the system has to be open to let authors choose their preferred tools; second, techniques such as „authoring on the fly" (a term first coined in [Maurer 1994] and successfully pursued by the group of Thomas Ottmann at Freiburg (see [Bacher et al 1996] for a concrete implementation and [Lennon et al 1995b], [Lennon et al 1994] for background ideas) has to be supported as much as possible; third, statistical information and feed back from students has to be provided by the system for the improvement of materials; and fourth, courseware has to be designed in a modular way so that it is easy to update and reuse.

It is the last issue that is maybe the most important yet often overlooked aspect. It is one of the many reasons why ordinary WWW where all the structure is built into the links cannot be seen as serious candidate for sophisticated MANKIND-like systems. A more powerful WWW system such as Hyperwave [Maurer 1996] is needed to be able to structure the material into modules (called „collections“ in Hyperwave) that can be reused and updated without the need to change any links to and from them. The HM-Data model [Maurer et al 1995a] is another step in the same direction and so is HOME (see [Duval et al 1995]). It is of extreme importance that we understand that in WWW we have to replace links by structure as much as possible in the same way as we have learnt that it is essential to use structure in programs (rather than goto's) and structure in handling data (rather than employing explicit pointers). Any person not realising that embedded links used for structuring purposes must not be used in sophisticated multimedia networked educational environments is well advised to consult the literature to fully understand the implications of what has been hinted at above.

Thesis 3: We need guidance but not dictatorship.
Early CAI/CBT systems were often suffering form the „tunnel syndrome“. When working through material you felt „locked in“, scarcely able to leave a predefined route, let alone look up electronic background material, have an electronic chat with others, etc.

The advent of hypertext/hypermedia (and WWW) turned this all 180 degrees around. Suddenly, there was unlimited freedom, a spaghetti-bowl of links to be followed, the „tunnel syndrome“ suddenly replaced by „lost in hyperspace“. Neither for teaching nor self-studies (and we return to those two separate aspects of the use of networked multimedia material in Thesis 10) do we want either of the above phenomena. For MANKIND this means three things: first, a certain amount of guidance through the material to be learnt is provided; second, at each moment in time control on where to continue rests with you, not the system; third, throughout the knowledge acquisition process the „guided path“ can be left in favour of many other activities (see Thesis 2 through Thesis 7), but in particular can be left to consult an electronic library residing in the background. Such electronic background libraries may range from a small selection of dictionaries, books, supporting multimedia material and software to very large electronic archives covering all kinds of knowledge. To be able to work efficiently, this knowledge again must be structured, and „search scopes“ depending on your personal profile must be definable, else the typical information overkill your experience with search engines on the Web is unavoidable. To fully exploit both the associative aspects of linking information and the search facilities and structure delivered by database systems, WWW systems with built-in databases are the most suitable solution for the issues mentioned, one other reason why Hyperwave was chosen as basis of MANKIND.

Thesis 4: Facilities for annotations are essential.
As you are working through some material, whether it is courseware in the classical sense, an electronic book, a library of pictures or what have you, you must have the possibility to add personal notes. Such personal notes could be text, pictures, arbitrary documents or even links to other material: how often has it happened to you that you found a piece of information x that you wanted to link to information y so that on revisiting x you would find your note and the link to y but you could not do so: after all, in ordinary WWW systems you cannot add links to documents that don't belong to you. In MANKIND - since it is based on Hyperwave - you can. And your notes (or links) are visible only to you, a group you define, or the general public, just as you decide.

Thus, annotations not only permit you to add notes as if „writing into the margins of a book“, they allow you some customisation (personalisation), a crucial issue that is the central point of Thesis 10.

Thesis 5: Facilities for asynchronous computer conferencing are imperative.
As important as it is to be able to take notes and attach them wherever suitable, it is still more important that others can read your notes, can comment them (i.e. attach their notes to yours), etc. Thus a general annotation concept as described in Thesis 4 actually leads automatically to the important tool of asynchronous computer conferences (ACC's).

ACC’s in their most simple version are like newsgroups or bulletin boards. However, often a better structure (to be able to follow the thread of a discussion) is preferable, even to the extent of supporting such „networks of annotations“ by tools that display a topic as icon and graphically show how many comments in any of a number of user defined categories („supporting example“, „counter example“, „supporting argument“, „counter argument“, „generalisation“, „special case“, „answer“, „related idea“, etc.) exist, what reactions those comments have provoked, and so forth. Note that annotations can be attached to a whole file (like a HTML page), or just to a particular part of text; they may be textual, but audio or video comments are equally conceivable: Observe further that one and the same document should be able to show a completely different set of annotations, i.e. different ACC’s, depending on the group of users accessing the document. MANKIND type systems will usually require some kind of identification (see [Flinn et al 1995]) to be able to distinguish various ACC’s. It is also desirable to combine ACC’s with mail systems. A minimal solution is to inform members of an ACC by email that new contributions have been added to the ACC. Observe that ACC’s are a natural extension of (semi-public) annotations and can be a major factor in any teaching and learning environment. It is often desirable to have „moderated“ ACC’s to avoid the possibilities of „disintegration“ of ACC’s that is sometimes observable. In passing we observe that ACC’s that are structured as a three-dimensional world you can walk around in to choose what interests you offer further new and attractive alternatives.

Thesis 6: Question/Answer dialogues should be possible where users need them.
In traditional CAI/CBT systems authors of courseware usually attempted to predict locations in the material that would require further elaboration (and would offer additional information if you decided you need help); or they tried to determine if you needed help by „asking questions“ and reacting to the answers received.

This „static model“ of question/answer dialogues is replaced in MANKIND by a much more dynamic approach. First, the system may ask you questions in the traditional sense, mainly for self-test and selection of material purposes as explained under Theses 9 and 10; secondly, and much more important, you as user can ask a question at any point as a kind of annotation: it may be a question to fellow students or to a tutor or teacher; and you may get immediate feedback if one of the persons addressed is currently on-line (e.g. if you ask a question during the official „electronic office hours“ of a tutor). Observe that the „technology“ for asking and answering questions may vary from text-only, to audio, video, or even 3 D, and may be affected by bandwidth, available hardware, etc. Thus, a general system should allow a „graceful“ degradation where necessary.

Thesis 7: An integrated teaching and learning environment needs synchronous communication facilities.
The possibilities alluded to in Theses 5 and 6 might leave the impression that no further communicative features are required. However, numerous experiments have shown that additional functions are required.

First, there is the need for „chatting“, where short individual contributions are not treated as separate documents but rather as one dynamically growing (and potentially non-persistent) document. Chats tend to degenerate often, particularly if there are more than a few participants. For this reason it is important to be able to initiate chats only with persons interested in similar topics. Typically, if you work through some chemistry material you may want to chat with fellow chemists, but not with persons currently working on Chinese literature. To be able to narrow down the set of persons potentially interested in a chat it is thus necessary to have the material in a MANKIND system systematically structured, as is e.g. possible using Hyperwave.

Secondly, chats alone are not enough. Of paramount importance is the availability of an electronic workspace (often in the form of a so-called whiteboard but in future also more and more in the form of 3D worlds populated by „avatars“ presenting other persons present) that can be shared by a number of users. Typical applications include a „follow me“ mode where one person leads others through some WWW pages, software package, etc., with „conversations“ between the participating persons going on at the same time. Such a workspace can also be used for co-operative work (on a piece of text, at graphic design in a 3D scene, or whatever) and is particularly useful for explanatory purposes: a question concerning a particular document can be answered and discussed in detail while this document is visible to all involved.

The „ideal whiteboard“ is open to all applications. I.e. you can run an arbitrary application in your whiteboard and whatever you do/see is visible to the group sharing the whiteboard with you. Unless the contents of the whiteboard is transmitted as a movie (e.g. 25 pixel images per second) whiteboards will only handle a certain set of applications. It might be worth mentioning that the whiteboard under development for MANKIND will e.g. support most of the HM-Card [Maurer et al 1996] functionality, including animation editing and question/answer dialogues, and 3D version are likely to be added, later.

Another important way of synchronous collaboration is found in so-called „decision room scenarios“. Typically, a topic is discussed in a strictly anonymous fashion (to overcome otherwise inherent fears of voicing unpopular opinions). Sometimes this is just done for „brainstorming“ purposes, sometimes the result may be an anonymous vote on how to proceed in a certain matter.

Thesis 8: Question/Answer dialogues should become part of the multimedia database.
As has been explained in theses 6 and 7 there are various ways how questions can be asked in a MANKIND system, and how and by whom they can be answered. While some of the dialogues (e.g. in the chat mode) might well be considered volatile (transitory) other question/answer dialogues should be archived for future use.

Typically, if a student asks a specific question and a tutor answers it, this question/answer pair should be recorded so that when other students ask a similar question later the system automatically can present the answer that might well have been given months ago! Clearly, if such a mechanism can be implemented, whatever material is at issue it will eventually be enriched by „all possible“ questions and answers to them. The difficulty clearly is how the system can recognise that question x is similar to question y. This is (almost) impossible even if x and y are text-only questions, and becomes still more intractable when x and y are formulated using spoken language. However, it has been argued in [Maurer 1996b] that by using the user's rather than the system's intelligence many of the problems can indeed be solved. Observe further that a piece of explanation that is soliciting many questions should probably be replaced by a better explanation, anyway!

Thesis 9: Testing and checkpoints are important.
It is, of course, conceivable that a system like MANKIND is enriched by a database of questions and answers and thus can also be used for examination purposes. To discuss the problems involved in this (e.g. from security to how the system evaluates whether a given answer is correct for questions that require more than the selection of a choice or the calculation of set of numbers) goes beyond the scope of this paper.

Note, however, that testing and checkpoints can and should be used for a variety of other purposes.

First, a pre-test can lead to selecting the proper set of „teaching modules“ in the right order (we return to this in Thesis 10). Second, material for self-testing is important for both material repetition (and hence retention) but also as indication to the users how much and deeply they have understood what has been discussed. Third, exercises - even very complex ones - are of high pedagogical value even if (as would usually be the case) the system itself cannot judge the quality of results: the system may present a number of good approaches, plus a number of bad ones - and leave further judgement to the user; the results may be checked (asynchronously or synchronously) by a tutor, or by fellow students, and students of tutors may even decide to incorporate good approaches permanently into the system. This leads to a fourth aspect, the aspect of voting and of „anonymous discussions“ much as mentioned in decision room scenarios at the end of Thesis 7.

Thesis 10: MANKIND cannot live without customisation.
The MANKIND ideas so far described present a fairly general and flexible integrated networked teaching and learning environment:

On the basis of existing modules new „courseware" is built rapidly and with high quality; you can peruse it at your own speed, and under your complete control; you can browse in background libraries, add notes for yourself and others, participate in discussions and votes, ask questions to fellow learners or tutors; and, in doing so, you increase the knowledge in the database and you provide important feedback; conversely, the system asks you for your participation, for completing exercises and presents tests that help you retain the material and show you your level of proficiency.

However, the most important aspect of MANKIND is still to be discussed: the aspect of customisation that makes the learning modules fit your needs: your needs will be different from the needs of others for at least three reasons.

First, different persons have different learning styles. According to the often quoted theory by Meeker persons belong to one of the three types: verbal, symbolic and visual. In a perfect environment each „module of knowledge" should exist in a verbal, a symbolic and a visual form. Depending on the individual learning and retention style (that can be determined by appropriate pre-tests) you should always receive modules that correspond to your learning style, a style you may wish to „override" once in a while. Even within styles there are differences.; you may prefer text to be visually displayed or spoken; often a few written words but a fuller audio explanation (if selected) may be the most desirable mode - particularly if you use the material not for self-study but e.g. for teaching others (in a classroom situation with a videobeam).

Second, different persons have different backgrounds. Learning material has to be broken up into very small modules. Intensive pre-tests should be used to determine which modules are useful in which order. This combination of modules depending on the person's background is only possible if links between modules are not part of the modules but e.g. available as structural information or such.

Thirdly, the environment (equipment, bandwidth, location of equipment, ...) and how it is going to be used (by a teacher, a student, a group of students, ...) will also influence the kind and format of the material applicable.

Putting this together, learning environments without customisation facilities can never provide satisfactory solutions. In a WWW environment this means that ordinary servers won't suffice unless an exorbitant amount of scripting is done. Hence the more powerful WWW solution Hyperwave was chosen as basis for MANKIND.

3. Summary

In section 2 we have presented ten theses; ten essential ingredients that we believe are minimal requirements for a solid integrated networked teaching and learning environment.

The ten theses are quite open-ended. Much work will have to be invested to achieve the points discussed, and many details (see e.g. [Maurer 1996b]) have not even been mentioned. However, a concrete attempt to implement a system called MANKIND on the basis of the theses is well under way. By combining Hyperwave [Maurer 1996a] and HM-Card [Maurer et al 1996] theses 1-6 and 9-10 have been implemented in first versions (and are indeed in successful use) while theses 7-8 will be ready in a preliminary form by end of 1997.

Abstract: This paper describes the design of an intelligent multimedia interface to enhance students' understanding of a particular lecture topic. This interface currently caters for the topic of Knowledge Based Systems. The package addresses the problem of lecturers not being able to interact directly with students due to the increased numbers of students on courses. This is achieved by enabling students to interact with the interface on a one-to-one basis and to access information from the interface which may have eluded them during the lecture. Thus teaching is supplemented with minimal time constraints, whereas class interaction or participation can slow down the delivery of teaching materials. The interface uses extensive multimedia facilities to present information in a manner which enables learning to be as effortless and enjoyable as possible for both able and disabled users. The interface was created using the HipWorks authoring application which makes use of the UNIX environment.

Key words: *Computer-Based Training, Multimedia, HCI*

1. Introduction

Computer-Based Training (CBT) systems have the ability to incorporate different technologies, such as video, sound, digitised images and animation. Such systems have been widely accepted in certain domains to help or supplement textual teaching such as lectures and seminars. This ability to invoke user participation through interactive means has made the approach an area for further development. One of the most important issues in education is the format in which information is presented to students. This application seeks to address this problem by concentrating on the usability of the interface. That is to say, a bad interface will have a negative effect on learning as it will not entice user interest and instead of being an aid to the learning process it will become a drawback and a hinderance.
Existing similar systems lack the complete interaction that is desired to encourage students to utilise such learning tools. In an attempt to eradicate this situation this application was based on the concepts of good HCI principles (Preece, 1994). Thus multimedia was incorporated to sustain the students' interest by demonstrating an interactive and intelligent learning environment to supplement the lecturer's teaching of knowledge based systems. The interest and interactivity of the student was generated through the integration of text, graphics, animation and sound which added an encapsulating dimension to the previously static lecture notes.

2. The use of hypermedia to encourage learning.

Although students may leave college with degrees, they *are taught superficially about great discoveries instead of being helped to learn deeply for themselves* (Kay, 1991), therefore some aspects of the teaching material will have been scantily understood. This application addresses this problem by presenting a dynamic interface through which a user can sustain interest and thus enlarge their concentration span over that of '*flat-text*' reading. In order to generate a more compelling environment, multimedia objects are built into this system using a interlinked hypermedia structure through which the '*flat-text*' syndrome is replaced by visually enticing

BEST COPY AVAILABLE

graphics, motion (video and animation) and sound. The multimedia objects which are incorporated into the system are characteristic of everyday living, exhibiting identifiable, representable and recallable properties, which induce productive interactive learning.

3. The Need for Lecture Support.

In a typical lecture a lecturer's role is to teach many students simultaneously in a lecture theatre. Hence, the teaching process is formal and time-constrained. This has an adverse affect on the learning process of individual students as each has their own '*information processing capability*' which may require a more informal approach to learning. Hence, there is a subsequent lack of student attention and information intake. Figure 1 below highlights the factors that were taken into consideration when designing the system.

• **Supported Activity**	- To encourage the interactive participation of students through an interactive interface.
• **Users**	- Third-level Computer Degree students - Able-bodied students - Disadvantaged students -Visually impaired - Mature Students[1]
• **Level of Support**	- Highly interactive hypermedia interface
• **Form of Solution**	- UNIX environment stand-alone CBT interface

Figure 1 Design Considerations

4. User Analysis

This interface is aimed at second year computer degree students and every different type of user within this domain must be accounted for, see Table 1. In today's society we have more and more people opting for continued or further education. Taking this into account, although the target audience will inevitably be studying computers, their whole physical and mental aspirations towards computers will be different. It should be noted that age is accompanied by a deterioration in the body's functions, and in particular, their eyesight and mental abilities. As stated by Morris (1994) '*there is a decrease in many physical, visual, and cognitive skills with age.* Therefore it was necessary to address these issues when creating the system interface so that the disadvantaged user would be able to benefit as much from the interface as the abled user. Also voice input is provided as Blanck (1994) stated that "*The speed and convenience of voice input enjoyed by mainstream able-bodied computer users often translates to greatly enhanced access and productivity for people with disabilities. The greatest benefit accrues to people with mobility and vision impairment.*"

---

[1] Mature students have been categorised as disadvantaged due to certain characteristics like loss in vision and reduced memory or information processing capacity. This is aimed at the more senior mature student.

Table 1: User Analysis

•User Characteristics

- student, also mature student
- professional or part-time student
- personal use
- important supplement to users' study schedule

•Skills

- high general computing skill level
- not all have UNIX skills
- general knowledge of such learning systems

•Conclusions

- keep interface simple and usable
- usability and functionality greater than for a text book
- minimise typing, and be quick and easy to learn

5. Usability factors.

It is necessary that the system adheres to usability factors. The following list identifies each usability factor that was taken into account and how it was considered during the systems design:
(1) ***Speed of Operation*** -This is quite important, but the speed of operation can be overlooked in favour of a better learning system.
(2) ***Completion Rate*** -Current lecture topics take on average 3 hours to be delivered. This tutorial system intends to deliver a topic within 30 -45 minutes depending on continued user interaction.
(3) ***Error-free Rate*** - The system has been designed to be as 'idiot' proof as possible. Any errors that occur are well documented by visual and auditory cues.
(4) ***Learnability*** - The system must focus heavily on this aspect. A user should naturally and quickly learn how to interact with the system. This should occur after the first interaction with the system.
(5) ***Retainability*** - The system must enhance the user's short and long-term memory. The user should not have to remember how to interact with the system as the system should be self-explanatory.

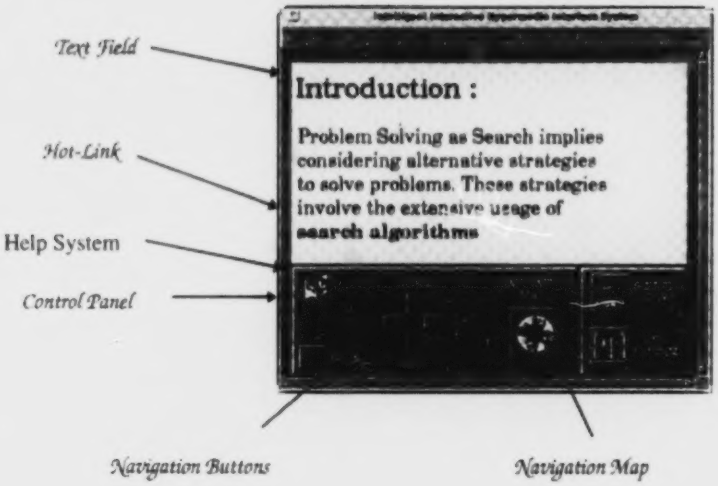
6. Hipworks and Prototyping.

Hipworks was chosen as the software development environment as it provided both hypertext and multimedia facilities thus enabling information to be presented in a combination of media formats comprising of voice, graphics, animation and text. Also Hipworks operates on a Unix platform which was advantageous as the Unix laboratory in the university was under-utilised and thus students could easily access a machine in order to run the application. Hipworks also was particularly suited to developing the system via prototyping.

As Gould (1988) points out , *'we miss things during analysis and simulation, and we rely on prototype testing to bring these out'.*
As usage (experience) comes before knowledge it was required to keep a set of student users (evaluators) to experience each deliverable of the prototype as it was made. As each interacted and found weaknesses or strengths, it was necessary to update the prototype to adhere to these findings.

7. System Implementation

The systems is composed of three sub-systems which are the help system, the system interface and the navigation system. The system interface was implemented first and then the other two sub-systems were added. Figure 2 shows the layout of the interface and all its components. It should be noted that the layout shown in Figure 2 is consistent throughout the system so that the user is not confused by different screen layouts.



Intelligent Interactive Hypermedia Interface System
Text Field
Hot-Link
Help System
Control Panel
Navigation Buttons
Navigation Map

Introduction :

Problem Solving as Search implies considering alternative strategies to solve problems. These strategies involve the extensive usage of **search algorithms**

Figure 2 System Interface

Text field: This component is very important to the system as it shows the information space of the system. This field presents the course material in an interactive way.
Control panel: This is where the navigation and other interactive system components are placed. Figure 2 illustrates the buttons for selecting the '*Help*' and '*Navigation*' facilities. The main components are the navigation buttons of '*Home*', '*Previous*', '*Next*', and '*End*'. Error messages appears only when for example the '*Home*' button is clicked or when the home page has previously been activated.
Sound ON/OFF: This is a toggle button which once depressed will either switch the sound 'on' or 'off', depending on its current state.
Navigation System : Navigation within all hypertext-based systems presents problems in terms of controlling the interaction path of the end-user so that the user never becomes lost whilst interacting with the system . This systems solves this problem by recording the students' interaction and offering a graphical display of the users' interaction within the information space (See Figure 3, below).

Indicator
Intelligent Interactive Hypermedia Interface System
Legend
Nodes

Figure 3: The Navigation System.

BEST COPY AVAILABLE

Each node is represented by a command button which when depressed will take the user directly back to that scene and the indicator then marks the users' current location within the system. This was achieved by making a text field invisible or visible when a user has entered the navigation area from that node. Also, the legend was developed through a label and text field.

Error Messages : Consideration was given to users who select an option that is unavailable or that cannot be invoked, for example if a dead-end has been reached.

Help System : An objective of the interface was to allow the end-user to have access to help at any point during an interaction. Therefore the help facility may be selected from any point during a user interaction. Once the help system is activated the user receives help by clicking on the appropriate hotword (See Figure 4, below).

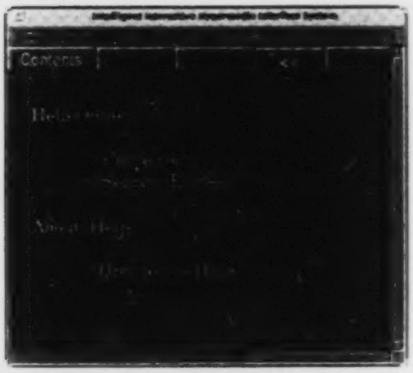


Figure 4. **The Help System**

8. Evaluation of the Interface.

The procedure for evaluating the interface involved users completing a questionnaire as well as directly observing how users interacted with the system. The questionnaire addressed the HCI guidelines (which were applied in designing the system) and the 5 deliverables as set out by ***Software Ergonomics in EC Directive 90/270/EEC*** (Anderson, 1996) which states that the interface must :

(a) *be suitable to the task,*
(b) be *easy to use and adaptable to users' level of expertise,*
(c) *provide feedback,*
(d) *have a format and speed of display which is appropriate to operators,*
(e) *have obeyed the principles of software ergonomics.*

The following observations were made in the light of these guidelines. It was discovered that the students thought that the interface presented no real difficulties for users in using the information space. However some students requested that more attention should focused on the expert user. For example the '*goto*' command allows direct access to any particular scene, but students thought that this was not evident from the interface and instead consequently they had to go laboriously through the menu. It was also thought that the interface would be extremely useful for the representation of CBT material but that extra functionality, such as permitting students to record their own on-line notes was found to be desired by some users. Finally, through direct observation, it was found that the initial reaction of the students to the interface seemed to one of interest. It was found that the interface enticed learning and was acceptable to all levels of users, in that even the first time users of the interface appeared competent in using the system. Disadvantaged users also were pleased with the interface especially the optional voice input, large text and uncluttered screens. It can be concluded from this that information that is presented through a hypermedia environment incorporating visual and auditory cues aids the learning process by providing a visually enticing learning environment which is much more interesting for the students than a text book.

BEST COPY AVAILABLE

9. Enhancements

A possible enhancement to the system would be the inclusion of a management system to guide the student through the tutorials and report back to the lecturer on the student's progress, the help that has been requested, and the results of the tests which are included in the tutorials. This aspect thus leads on to an important implementation strategy known as '*Distributed Multimedia*' or in the case of CBTs '*Distributed Teaching*'. This management system would be best utilised in a network environment where lecturers could be contacted directly via an e-mail mechanism. Statistics could also be gathered from this distributed approach, and will offer greater flexibility to the user than stand-alone interaction. Another enhancement to the system would be to make the system adaptive. For example an '*intelligent*' mechanism could be added through which the user's interaction would be monitored by the system and determine the level at which to aid the user (this is dependent on whether or not they are in fact expert or novice users). This would eliminate standardisation of the interface and instead customise the interface to fulfil the requirements of each user.

Evolution of an Educational Database: From Telidon to CD-ROM to Virtual Reality on the Net

Linda McCormick
Dissemination Division
Statistics Canada
Canada
mccolin@statcan.ca

Abstract: The success of an electronic product or educational software depends on the author's ability to provide relevant information, respond to technological developments in the classroom and support the teaching/learning process. This paper explores these issues and their resolution during the development of an educational database intended for secondary students. The product was created by Statistics Canada in response to a request from the education community for timely access to social and economic data on Canada. It has evolved from an on-line database, to a stand alone CD-ROM and, in the fall of 1997, will have come full-circle, to an on-line web service.

Evolution

Originally called CANSIM/Telichart, the project resulted from a request from a single school. Richmond Hill High School was interested in data and "real-life" computer technology. They approached Statistics Canada in 1986 and were granted direct access to our main database through a VAX computer. Telichart enabled users to select and display data as a chart or list. Users could perform basic calculations and some analytical functions such as moving averages and regressions. No one could describe the system as user-friendly: documentation was a number of 3-inch binders containing data series identification numbers and a two-page list of commands. Support consisted of a number of on-site visits and telephone contacts.

Intended for Business Studies, the project quickly caught the attention of teachers in other subjects such as geography, history, economics, family and social studies, mathematics and computer sciences. The degree of interested caught us off guard; our enthusiasm for tables of numbers is not shared by many people. Senior management at Statistics Canada believed the project offered a unique method of fulfilling our mandate, while supporting the provinces' educational objectives to improve students' knowledge of Canada, facilitate the development of analytical abilities and advance computer skills.

For the benefit of international participants, education in Canada is a provincial responsibility, while the centralized statistical system is funded by the federal government. Even though Statistics Canada, the central statistical agency, is apolitical and has an arms length relationship with policy departments, it must tread very carefully in provincial jurisdictions. Many decisions taken during the development of this product reflect the boundary between federal and provincial responsibility

Encouraged by the success at Richmond Hill, we began field testing with three additional sites in the Ottawa area, then expanded the test to 40 sites across Canada in 1990-91. The documentation was expanded to include a user's guide, a quick reference card and examples of how teachers use Telichart. Support remained the same.

Two main issues were brought to light by the field test. The delivery system was identified as a problem by both users and providers. Educators liked the interactive feature of the system but were concerned that connection charges could become onerous. From our end, the number of sites who could connect to the VAX was limited. Both groups felt improved documentation was needed. Educators wanted immediate access to direction and technical support, while we felt on-site visits would be physically, as well as, fiscally impossible if the product went into wide distribution.

The delivery system problems were resolved by developing a stand alone product. Fortunately, the increasing number of schools owning CD-ROM readers allowed us to consider this option. Renamed E-STAT, the CD-ROM stored current and historical data on Canada and Canadians including results from the 1991 Census. The first version was released in 1992 using DOS-based software to select and present data as tables, graphs or maps.

Spirit of cooperation that gave birth to the product in the first place continues. To broaden access to E-STAT, Statistics Canada has actively pursued licensing agreements with all the provinces and territories. Seven provinces have signed licencing agreements which have the effect of lowering the price to individual schools. An agreement with British Columbia, required the development of a Web version of E-STAT. This version is being filed tested and eventually will be available through our Web page as a subscription service. Subscribers will also be given a CD-ROM which may be networked or run as a stand alone.

Providing Information and Keeping it Relevant

Given our mandate to report on the social and economic well-being of Canada and Canadians, Statistics Canada can provide a wealth of information and, unlike many other application authors, does not have to apply for copyright approval. Rather than tailoring subsets of data to match curricula, we decided to rely on educators to select what they need. We actively seek partnerships with other departments, levels of government, business and individuals.

The success of E-STAT and its predecessor is largely the result of individual champions working in their schools. We continue to capitalize on this type of relationship by supporting any initiatives with our in-house resources in return for permission to publish or otherwise disseminate the outcomes. Listening to the feedback from these champions and implementing their suggestions has been an important feature of the development process.

One of the first comments we heard was "delivering data is not enough; it must be integrated in the curriculum." Materials developed during the Telichart phase and various field tests were included with the first version of E-STAT, and elaborated in each succeeding release.

Feedback is often contradictory. For example, some users feel there are too much data on E-STAT, while others ask us to include more data on specific topics. Early on we decided to maintain the original level of detail and, in fact, to add data from other sources believing this would better serve a national audience. However, the volume of data can be overwhelming so every effort is made to help users pinpoint the data they need. Changes are made to both the software and the documentation on an annual basis to improve the accessibility to data. School librarians pointed out the difficulties with our keyword search, as a result we have developed a topic list which is closer to the terminology used by students.

A portion of our University Liaison Program (ULP) focuses on Faculties of Education. The universities receive E-STAT and agree to provide information on its use by staff and students and suggestions for improvement. The coordinator also works with individual professors delivering training, facilitating access to subject matter specialists at Statistics Canada and encouraging academic endeavours. Several professors have spent parts of their sabbatical at Statistics Canada. The ULP sponsors two award programs. One recognizes excellence in curriculum design by pre-service teachers. The other is offered for graduate student research and is offered jointly with the Canadian Society for the Study of Education and the Canadian Educational Research Association.

Formal avenues are also used to evaluate E-STAT when a strong trend in the feedback becomes apparent. The earliest versions of the CD-ROM are a case in point. Dr. B. Griffith and Dr. J. Paul of the University of Calgary conducted a survey of users in the Western provinces. The first section in their report provided information on who purchases/uses E-STAT. "Overall it is safe to say that the responders are mature, very experienced teacher-librarians or male administrators who have a high level of university training and regard themselves as computer literate." The second section of their report summarized respondents comments on the product. "Although some of the purchases and users have acquired various document packages with their purchases, there was no indication that any of the options or packages was consistently helpful .... most respondents in Section B spoke of E-STAT in terms overwhelmingly as "not user friendly". This persistent comment permeates the survey responses."

Many of the problems identified in the first release of E-STAT were corrected in subsequent editions. However, to balance rapid advances in technology and limited resources for development, Statistics Canada decided to skip to an Internet version of E-STAT rather than develop a Windows version.

Technological developments in the classroom

A number of issues surface under this heading. First, technology in Canada tends not to be in the classrooms. Rather, it is housed in computer labs or school libraries. We have been rather slow to realize this fact; much of the E-STAT documentation is targeted to individual teachers working in their classroom. Only now are we beginning to develop materials and strategies which a librarian can use with students or teachers.

Second, new technologies are adopted slowly by schools, but enjoy a considerably longer life than in the business world. Also, purchasing decisions are local, most often school boards choose one format, but occasionally we will find a school with both MAC and DOS-based machines. E-STAT is currently available for both MAC and DOS platforms on the Web. We expect to continue supporting all of these formats for sometime.

Third, the computer literacy of educators may prove to be a barrier. Recent survey results show that seven of 10 secondary school teachers report using computers but for an average of less than 10 hours a week, suggesting that their comfort level is not high (Oderkirk, 1996). These findings confirm our field experience. E-STAT is interactive and, therefore, requires a fairly sophisticated user. Much of our work is now focussed on developing classroom-ready materials and training educators.

Supporting the teaching/learning process

We are building an inventory of lesson plans written by professional educators. The activities are curricula based and specific keystroke commands are embedded in the student handouts. They are published in the teachers resource which is part of the E-STAT documentation. Feedback has pointed out that the CD-ROM and printed materials often get separated so we began posting the materials to our Web site with the 1995 version and including it on the CD itself with the 1996 version. All of our materials are covered by a blanket copyright approval allowing unrestricted use for nonprofit educational purposes.

Another method we have used successfully to reduce anxiety and encourage educators to use new technology is to conduct workshops and recommended teaching strategies. Although the following strategies were developed around E-STAT, they can be applied to many types of electronic products.

Hands-on workshops in the lab or classroom

Over the last several years, Statistics Canada has developed a workshop format to introduce in-service and pre-service teachers to E-STAT. We recommend that a similar format be used with intermediate or senior students.

The optimum lab configuration is one computer for every two or three participants. (One student reads the instructions, the second operates the keyboard and the third verifies the actions of the operator and records results.) The best lab arrangement is u-shaped or widely spaced rows that allow the instructor to view each computer screen easily.

Using one of the computers and a LCD panel or a 20" monitor, the instructor demonstrates an E-STAT lesson giving a running commentary on the keys being used. Participants are asked not to use their computers until the demonstration is complete. The same exercise which includes specific computer instructions is provided to all participants. Participants complete the activity on their own.

BEST COPY AVAILABLE

Workshops usually include two activities one for each of the main databases on the CD: CANSIM Time Series and 1991 Census of Population. Generally, a DOS workshop can be completed quite handily in two hours, while a MAC workshop can be completed in 1.5 hours.

Preprinted maps, graphs or worksheets in the classroom

In many schools, scheduling time in the computer lab can be difficult or impossible. Instead of taking a class to the lab, it is possible for the teacher to bring the data to the students by using the keystroke commands in the lesson plans to create worksheets, graphs or maps. Printed copies can be distributed to the students for analysis along with the activity sheets containing the actual assignment.

Single workstations

Another method would be for the teacher or E-STAT student coach (see the item below), to store a series of maps or graphs on a classroom, lab or library computer using E-STAT's saved graphs and maps function. Students can be referred to this computer as a workstation for an assignment. They retrieve the saved items for analysis. This approach reduces the demand for scarce computer resources and almost guarantees a successful experience.

Student Coaches

Given the proliferation of educational software and reduction in technical assistants in most school boards, many teachers find the suggestion to use students as coaches intriguing. The objective is to let a few students train themselves in how to use E-STAT. The self-training might be an option to replace a major assignment in any course or offered in a computer skills course. The teacher uses a checklist to test the student's knowledge. Those students who pass are certified as coaches and may assist their peers.

Train the Trainer Workshops

Licencing agreements often include a training component for in-service teachers. After the training has taken place in the sponsoring province, it is adapted and made available to all regions of the country.

Conclusion

An electronic product designed for the education market must be dynamic but its development must keep pace with adoption of technology by schools and educators. The product should also facilitate the learning process for both teachers and learners. Formal and informal partnerships are necessary to ensure the product stays current and relevant.

Australia
C.McNaught@latrobe.edu.au

Abstract:
This paper will attempt to draw together two threads in current educational literature—a general literature on students' approaches to learning in higher education, and a growing collection of descriptions of and reflections on the use of computer-facilitated interventions for the enhancement of student learning. A model of student learning will be presented where the importance of students' approaches to learning is emphasised. Evaluation data from several computer-facilitated projects will be presented in terms of how students develop and modify their approaches to learning.

Introduction

There is now a substantial literature on why computer-facilitated interventions should enhance student learning. Much of the actual evaluation which supports assertions of enhanced learning is superficial and based on questionnaire and interview data about student attitudes to the new material. We have a range of exciting designs designed to encourage new learning modes and strategies, but insufficient understanding about how students actually go about the learning process in these new learning environments. There is little information about how students operate in computer-facilitated learning (CFL) environments—what sort of approaches they adopt, and how these approaches might be modified when new strategies are adopted. In this paper I will look at three general methods which can be used to gain information about student approaches to learning in a CFL environment—questionnaires, interviews and mapping of audit trails.

A model for student learning

[Biggs 1989] presents a model for student learning in terms of three types of components—those which exist prior to learning (Presage factors) such as existing student characteristics and the overall teaching and learning context; the Process factors relating to how students and teachers approach their respective tasks; and the Product as student learning outcomes. Biggs presented this '3P' model in two ways—as a model of student learning and applied to teaching. In figure 1 [Fig. 1] I have combined these two representations into one heuristic model which indicates clearly how student learning relates to both student and teacher perceptions and approaches.

As [Biggs 1989], [Biggs 1993] makes clear, we should not view this model as a linear progression. Rather, it is a dynamic, interactive system with changes in any factor affecting other factors. Understanding the influences of curriculum design on student learning is a complex issue and several factors need to be considered, for example:

- courseware design for the overall set of learning experiences [Lajoie & Derry 1993];
- the nature of teacher-student, and student-student interactions [Crook 1994], [Laurillard 1993];
- approaches to assessment [Ramsden 1992];
- skills and approaches of teaching staff [Samuelowicz & Bain 1992], [Trigwell et al. 1994], [Bain & McNaught 1996]; and
- relationships between teaching approaches in one subject to other subjects in the course [Wills & McNaught 1996].

Student Approaches to Learning

There is a well-developed collection in the general higher education literature on students' approaches to learning—for example, the work of Biggs and others about students' adoption of surface, deep or achieving approaches to learning. In surface or reproductive learning understanding is limited in scope and is not integrated into students' existing knowledge frameworks. Students wish to avoid failure but don't work too hard. Deep learning involves the refinement and assimilation of understanding; this can enable students to feel confident in applying knowledge and/or to be critical in evaluating new ideas for themselves. Such students tend to read widely, discuss and reflect. An achieving approach is a pragmatic approach where working within the prevailing system to maximise achievement dominates students' decisions about study. An achieving approach does not preclude deep learning; rather it reflects students' dominant concerns about learning in higher education. These approaches have been identified in several studies, e.g. [Biggs 1979], [Biggs 1989].

Case Study 1: Practical Physiology: Questionnaire Data

The second year undergraduate practical physiology course for science students at The University of Melbourne was radically revised in 1994. The new course was designed with an emphasis on scientific method rather than on the development of explicit skills or learning factual knowledge. Each topic now covers a three-week cycle of pre-practical work, experimental work and post-practical follow-up. Computers are used in the laboratories to streamline data acquisition and processing, provide on-line help using multimedia resources, and provide feedback and quizzes. In 1994 questionnaire data was collected on:

- student perceptions of the aims of the course at the beginning of the course and after experiencing the practical course and associated lectures, and
- student approaches to learning.

Questionnaires with open-ended questions were administered during the first and final weeks of semester 1. 136 students filled in the questionnaires. The overall picture was a positive one. Three-quarters of the students seem confident that they have learnt important skills and that the structure of the course is a useful one. A modified version of the Course Experience Questionnaire (CEQ) [Ramsden 1991] was given to the students at the end of the course. The CEQ has five scales—good teaching practice, emphasis on independence, clear goals, appropriate assessment, and appropriate workload. These five scales have been extensively trialed and have been shown to be reliable and valid performance indicators for teaching quality in higher education. Students' perceptions of the learning environment were positive on all scales [McNaught et al. 1995].

So, in this computer-facilitated environment, that students consider to be valuable, how do they approach their study? In what way has this experience altered their perceptions of how to approach studying physiology?

A questionnaire was given to students at the end of two semesters of the new practical physiology course. The ten items selected were based on the Study Process Questionnaire [Biggs 1987]. Ten items only were chosen because of concerns about questionnaire fatigue. The items chosen, and an interpretation of the student responses are given in table 1 [Tab. 1]. In the comments column the predominant approach is classified in terms of whether the majority of students appear to adopt surface, deep or achieving approaches to learning. There were 50 respondents.

An achieving approach to learning is strong with this group of students. There is a strong rhetoric about deep approaches and holistic understandings in university education, but the reality is that even a course that students find satisfying and interesting is only one small section of their experiences of learning and can make relatively little impact.

Question	Comments
1. I think browsing around is a waste of time, so I only study seriously what's given in the practical manual.	achieving
2. While I am studying this practical course, I think of real life situations in which the material I am learning would be useful.	achieving -> deep
3. I learn some parts of this practical course by rote, going over them till I know them by heart.	surface -> achieving
4. I feel that this practical course became interesting once I became involved in studying it.	deep
5. In studying this practical course I am focussing more on the procedures than the theoretical material.	achieving
6. I try to relate what I have learned in this practical course to material in other sections of the physiology course.	deep
7. I think it is only worth studying material which I know will be examined.	achieving
8. I believe strongly that my main aim in studying this practical course is to understand it for my own satisfaction.	deep
9. I am prepared to work hard in this practical course because I feel it will contribute to my employment prospects.	achieving
10. Studying this practical course has challenged my views on how the world works.	achieving -> surface

Case Study 2: Veterinary Microbiology: Interview Data

This innovation involved the development of interactive, multimedia databases of veterinary curriculum materials, linked to a revised set of educational objectives, a range of other learning situations and more appropriate assessment procedures. The expanded set of learning objectives required students to acquire information management and problem solving skills, as well as understanding bacterial and fungal diseases of animals. The development of group learning skills and communication skills were also explicitly built into the course. The curriculum rationale is explained in detail in [Whithear et al. 1994]. In this computer-based, case study learning system (CB CS LS), 24 lectures, 40 hours of laboratory sessions and course notes over 8 weeks were replaced by no formal lectures; course material in multimedia databases; 40 case studies with associated quizzes, 6 of which were intensive laboratory exercises (10%); 5 short essays (20%); 1 seminar (5%); literature review (15%); and 1 'open computer' examination (50%) (assessment percentages in brackets).

Evaluation [McNaught et al. 1994] indicated the following positive outcomes:

- Students took more responsibility for their own learning. They were expected to acquire new information from a variety of sources, including primary sources, and to develop skills to control their own information using a computer.
- There was no requirement to memorise by rote. Learning was predominantly contextual, using simulated, problem-based case studies.
- Higher order cognitive skills were sought and demonstrated in the presentation of seminars and essays, and in the 'open computer' examination answers.
- More opportunity was provided, and emphasis placed, on collaborative learning.
- More opportunity was provided for students to develop written and oral communication skills.
- Continuous monitoring and feedback (both quantitative and qualitative) of student progress was provided.
- Increased awareness of, and interest in, the subject and improved practical skills were demonstrated in this class compared with previous experiences with classes taught in the conventional manner.
- Students acquired familiarity and skills with computers and computer networks.

In this radical curriculum shift what can we learn by interviewing students about how this change might have changed their approaches to learning?

The richness of this qualitative data is often undervalued. Initial reservations about this new learning style were strong. This 'culture shock' is a main element in implementation and, initially, this factor was underrated by the project team. Students can experience a culture shock with educational innovation. They have the idea that they've been trained and rewarded for a particular style of learning which has focussed on memorisation—that this *is* effective learning. Students' acquired model of learning is thus at variance with many innovative ideas which focus on interdisciplinary studies, teamwork, and deep learning. This disjuncture can create difficulties, perhaps more than people realise at the outset. In a session on collaborative learning early in the course, the following student quotes were obtained from walking among the groups who were talking about how they had previously learnt things.

- *I don't learn anything which is not Veterinary Science.*
- *We're too busy in the course to do any thing else.*
- *If you get together in a group you only waste time.*
- *I'm intending to learn the course this way: I've got all last year's notes from the student who did this course last year and that's the way I'm going to learn the course. I don't think these case studies are going to do much for telling me how to save a cow in middle of the field at midnight. I'm going to be reading those and memorising those notes.*
- *I'm competitive and individualistic and have been rewarded for this so far. I don't want to change.*
- *I'm already a good information manager; otherwise I wouldn't be here.*
- *Well, there's social skills you might learn in a group and there's intellectual skills, and they're all quite different.*

This was a difficult and intense session but brought the idea of talking about how one learns out into the open. At this stage, many students were clear that they didn't see conceptual learning as being something which involves interaction. This became an ongoing discussion throughout the course and contributed to the positive outcomes. We certainly feel that this open exploration about learning is unusual in veterinary courses and of real benefit.

About a third of the students did find the session interesting.

- *Yeah, this was worthwhile. I don't know. I haven't had any experience of this sort of thing because I've always learnt individually, but this has given me something to think about.*
- *But it was useful to talk about reflection.*
- *All this learning stuff ... we've done before; it was all pretty elementary really. In general, it was all common sense.*

These comments can be contrasted with the more positive and pragmatic comments made in the group 'debriefing' session at the end of the 1993 course. This workshop session enabled students to amplify any points they wished. The 'baldness' of categories from a questionnaire are thus overcome and the possibility of accurately describing students' position on any issue was greatly enhanced. Students expressed clear appreciation at this opportunity to be involved in evaluation. Their appreciation of the efforts made by staff in the course was very high. They commented on the range of learning styles that students may adopt and felt that the course structure provided a flexibility that allowed students to develop their own strategies for organisation and learning; for example, by individualising their study habits, by timetabling their out-of-hours computer sessions and by structuring protocols for their group activities. During the course, significant shifts had occurred on students' approaches to learning.

The evidence the project team has it that these shifts were not sustained. One eight-week experience is unlikely to alter students for long when other subjects encourage information reproduction.

Case Study 3. First Year Chemistry: Visual Mapping of Individual Questions

ChemCAL is an interactive computer-based tutorial package for the teaching of introductory and first year tertiary chemistry. ChemCAL software [Fritze & McNaught 1994] uses on-screen video and animations, a range of question formats and three levels of direct response to students; it also has built-in logging that provides two-way feedback to both students and course supervisors.

All the ChemCAL modules are designed to assist students towards the development of a deep understanding of chemical concepts and of an integrated understanding of the relationships between topics. To help achieve these aims, there is a high level of interactivity coupled with detailed assistance available to students in all modules. There is very little straight didactic material. There is also a large amount of visual material present in the modules as animations and video clips, designed to help students develop their own mental models of the central concepts of chemistry. Approximately 70 hours of instructional material have been developed to date. Evaluation has indicated positive outcomes [McTigue et al. 1995].

Visual mapping of student audit trail files [Fritze 1994] can be used to examine the actions of students. In this example, a single screen of one chemistry tutorial will be discussed. The question required that they enter the correct structural name for an organic molecule presented in diagrammatic form. At any stage, the student has access to various levels of assistance (in addition to summoning the real life tutor!). Students were familiar with the program's operation having completed six previous modules. For each item students can ask for a hint, ask for an explanation, ask for an answer to be checked or make a comment.

Once the first question item has been completed correctly, another one is displayed. For this question there are eight items, labelled 'EFLDq1' to 'EFLDq8' in figure 2 [Fig. 2]. Figure 2 [Fig. 2] provides two contrasting student styles. Student A shows a determination to complete each question item alone, making heavy use of support information provided before eventually attaining the correct answer. Student B, on the other hand, has requested the solution in all but item 3. It is tempting to infer that student A is adopting a deeper approach than student B. Clearly this is insufficient evidence but viewing large numbers of these maps does enable one to get a sense of student strategies and approaches. They can be viewed as a Quicktime movie. These maps are also an excellent stimulus for post-session interviewing [Fritze & McNaught 1966].

Three methods of collecting data about students' approaches to learning have been presented here—questionnaires, interviews and visual mapping of student logs. All methods provide insights into student approaches to learning. Further emphasis on this aspect of evaluation is needed. There is evidence that using well-designed CFL can encourage deep approaches to learning but the strategies need to be reinforced in several areas of the students' experience. One-off experiences do not result in lasting changes.

PREFACE

Welcome to ED-MEDIA/ED-TELECOM 97 in beautiful Calgary, Alberta, CANADA. It is fitting that this tenth in a series of research and development conferences is being held in the same city that hosted the first meeting, the International Conference on Computers and Learning (ICCAL) in 1987. Over the last decade, thanks largely to the efforts of scores of volunteers, ED-MEDIA/ED-TELECOM has become one of the top events of its kind anywhere in the world. An annual event since 1993 when the conference became associated with the Association for the Advancement of Computing in Education (AACE), ED-MEDIA/ED-TELECOM retains many valued aspects of the earlier conferences, most importantly the truly international nature of its participants. At the same time, the conference has grown in sophistication and scope, and we hope that you will find that this year's version lives up both to your memories and your expectations.

In areas as heavily invested in innovation as educational multimedia, hypermedia, and telecommunications, some might question the meaning and value of holding face-to-face conferences for which presentations must be submitted and prepared months in advance. After all, changes in the technologies we employ occur at a faster and faster pace, and last month's cutting-edge news is this month's dull topic. However, most of us recognize that as conference participants we are not so much interested in technologies as ideas. New ideas are often shared, critiqued, and reshaped through personal dialogue and group discussion. Further, we recognize that many of the most important exchanges that take place at professional meetings occur away from formal sessions. Collegial introductions at social events as well as chance meetings in the hall where you make new friends and catch up with old ones, these and many other human interactions are often the most valued and long-remembered aspects of any conference. Although the global "infocasm" described by futurists suggests otherwise, we predict that the basic human need to interact face-to-face will last far into the 21st Century.

As co-chairs of the Program Committee (PC), we have endeavored to increase the quality of the papers, tutorials, workshops, posters, demonstrations, panels, showcases and other events at this year's conference. We could not have done this without the hard work of the PC members listed on the following pages. Representing nearly twenty different countries, these individuals reviewed more proposals than ever before. The papers in this volume and on the accompanying CD-ROM survived several rounds of demanding analysis, critique, and selection, as did the other types of sessions. In addition, the counsel of the Steering Committee members was invaluable, especially in terms of selecting the keynote and invited speakers. Gratitude also goes to the AACE team, most notably Executive Director Gary Marks. Finally, we acknowledge the many and varied efforts of the Local Executive Committee in Calgary, co-chaired by Brian Gaines and Douglas Norrie, of the University of Calgary, our host institution. Thank you one and all.

A year of preparation will soon be over, and ED-MEDIA/ED-TELECOM 97 will be a memory. It is our hope that this memory will be refreshed each time you open this volume or access the conference CD-ROM, seeking information and inspiration for your future work. Further evidence of that living memory will be your continued participation in this event. To that end, we look forward to seeing you again next year at ED-MEDIA/ED-TELECOM 98 in Freiburg, Germany.

◆

TABLE OF CONTENTS—VOLUME II

Maria Emilia Xavier Mendes & Wendy Hall
The SHAPE of hypermedia authoring for education 733
Ananda Mitra
Categories of computer use and their relation with attitude towards computers 739
Eugenio Morreale, Teresa Berni, Circolo Didattico; Federico Carubbi, Marco Franzini, Giulio Tagliaferri, & Marco Zuffi
Teaching natural sciences in primary school: The role of a museum 745
Antoinette J. Muntjewerff
Learning to solve legal cases with the application PROSA 751
Ann Nishioka & Mike Eisenberg **(Award Paper)**
Paper modeling from a distance: Computational crafts on the Web 757
T. Nisiki & A. Tsubokura, M. Ueno, & K. Tsushima
Man-machine communication using Eye Movement 763
Jane Noel & Mary Lynn Brannon
Implementing collaborative learning through mainstreaming faculty use of technology 771
Victor Nolet, Gary Marchionini & Ernestine Enomoto
Full motion video and a dynamic query in a networked learning community 777
Gregor M. Novak & Evelyn T. Patterson
Motivating and retaining students while enriching their learning experience: Just in time learning with the World Wide Web 783
Jennifer J. Ockerman, Lawrence J. Najjar & J. Christopher Thompson
Evaluation of a wearable computer performance support system 788
Toshio Okamoto & Akiko Inaba
The intelligent discussion coordinating system for CSCL environment 794
Kevin M. Oliver & Lara Luetkehans
Alternative means of Internet access: Enabling financially-strapped public schools 800
Kevin M. Oliver, Gene Wilkinson & Lisa Bennett
Evaluating the quality of Internet information services 806
Ron Oliver, Arshad Omari & Jan Herrington
Exploring student interactions in collaborative World Wide Web learning environments 812
Ron Oliver & Murray Lake
Training teachers for rural & distant education: Using authentic and meaningful contexts 818
Tim O'Shea, Randall Smith & Eileen Scanlon
Exploring the scaleability of object-oriented environments that support synchronous distributed collaboration 824
Mathew J. Palakal, Carla L. Boyd, Frederick W. Myers & Ted D. Biggs
PACER (Personally Active Computing Exploration Resource): The development of an interactive learning system using object-oriented programming methodologies and JAVA 829
Jonah H. Peretti
The interactive story: Fostering school community through multimedia projects 835
R.A. Phillips, N. Jenkins, G.M. Fyfe & S. Fyfe
The user interface design of learner-centred interactive multimedia programs 841
Michael Pichler, Peter Sammer, & Michael Gruber
Animation of the great hall of the Austrian National Library 847
Seppo Pohjolainen & Heli Ruokamo-Saari
Distance learning in multimedia-networks: A Finnish national multimedia project 853
Ilona Posner, Ronald Baecker & Bruce Homer
Children learning filmaking using multimedia tools 858
Nelson De Luca Pretto
Reducing distances for face-to-face education 864
Blaine Price & Marian Petre
Large-scale interactive teaching via the Internet: Experience with problem sessions and practical work in university 869

Alejandro Ramirez
The design of a cognitive flexible hypertext learning aid to teach a structural model of implementation . . . 875

Samuel A. Rebelsky
CourseWeaver: A tool for building course-based Webs . . . 881

Lucio Rehbein, Enrique Hinostroza, Miguel Ripoll & Pedro Hepp
Hypermedia software impact in young students . . . 887

Ilju Rha & Insung Jung
Making connections: Interactive videoconferencing technology in distance education . . . 894

Mark Riordan, Vincent Wade, Allan M. Krebs, Jorgen Boegh,
Morten Wagner & Anders Gammelgaard
Tele-educational services in a future open service market . . . 900

Scott A. Robbins
Implications of distance education as an agent of sociocultural change . . . 906

Wolff-Michael Roth
Phenomenology, cognition, and the design of interactive learning environments . . . 911

Maria Roussos, Andrew Johnson, Jason Leigh, Craig R. Barnes,
Christina A. Vasilakis & Thomas G. Moher **(Award Paper)**
The NICE Project: Narrative, Immersive, Constructionist/Collaborative Environments for learning in virtual reality . . . 917

Heli Ruokamo-Saari
Mathematical giftedness and development of mathematical word problem-solving skills in a technology based learning environment: A teaching experiment . . . 923

Djamel H. Sadok, Judith Kelner, Fernanda Bezerra, Cavalcanti Marques &
Jose Marconi de B. Lima
An authoring paradigm with parametrization and project design support . . . 928

Flavia Santoro, Neide Santos & Lidia Segre
Young learners and cooperative authoring . . . 935

Steve Schlough
An analysis of the knowledge, skills, and attitudes needed in a computer supported cooperative work environment . . . 940

Lynne Schrum **(INVITED SPEAKER)**
Creating collaborative learning environments: The challenge for distant learners . . . 946

Kamran Sedighian **(Award Paper)**
Challenge-driven learning: A model for children's multimedia mathematics learning environments . . . 952

Royston Sellman
Java and educational simulations: Saboteur or saviour? . . . 958

Robert Sheehan
Designing a Web browser for children . . . 966

Cathie Sherwood
Multimedia courseware for teachers: Providing flexible professional development . . . 971

Cheryl Silverstone
Singing with software: The use of computers and music in early childhood vocabulary development . 977

Julean A. Simon & David C. Wohlhart
Object orientation in discourse structuring . . . 984

Alan F. Smeaton & Francis Crimmons
Virtual lectures for undergraduate teaching: Delivery using real audio and the WWW . . . 990

Masato Soga & Kenzi Watanabe, Toshinari Tanaka, Makoto Sakamoto,
Hideaki Tanaka, Shinji Toyomasu, & Masami Okyudo
A framework of remote telescope system by WWW with computer-assisted guidance and instruction . . . 996

Mia Stern, Jesse Steinberg, Hu Imm Lee, Jitendra Padhye & James F. Kurose
MANIC: Multimedia asynchronous networked individualized courseware . . . 1002

Sue Stoney & Ron Oliver **(Award Paper)**
Making interactive multimedia appealing to adult learners . . . 1008

S. Augustine Su, Shueh-Cheng Hu & Richard Furuta
VRML-based 3D topographic maps: Enhancing educational applications . . . 1014

KATHLEEN M. SWIGGER & ROBERT BRAZILE
Intelligent agents for teaching people how to cooperate 1020
PETE THOMAS
Electronic audio-graphic tutorials: A teacher's perspective 1026
JUDI THOMSON, JIM GREER & JOHN COOKE
Proxy servers and databases for managing Web-based education 1034
GUILLERMO VASQUEZ DE VELASCO & JAVIER JIMENEZ TRIGO
Compressed video technology in International architectural reviews: An instructional application 1040
IRIS VAN DE KAMP, BETTY COLLIS & JEF MOONEN
A model to assess the value of WWW based applications in stimulating productive engagement by students 1046
JAN VAN DER VEEN & BETTY COLLIS
Telematic tools to support group projects in higher education 1052
KIM H. VELTMAN **(KEYNOTE SPEAKER)**
New Media in the Post McLuhan Age: A System for Universal Media Searching (SUMS) 1058
ROB WALKER
Flying in the face of instructional design (rationale for the case study) 1077
MARTYN WILD
Building knowledge acquistion into the Web 1083
MICHELLE WILLIAMS
Connecting teachers — A professional development model in a distance education context 1089
JANICE WOODROW & JOLIE MAYER-SMITH
Technology enhanced instruction: A model for improving Science teaching and learning 1096

PANELS

ALI A. HUSSAM
VR: A tool to supplement education 1102
KAREN (SAM) MILLER, MARY ANN KOLLOFF, & CAROLYN RUDE-PARKINS
Instructional design for distance education: How to maximize your effectiveness over distance 1104
DOUGLASS SCOTT, ROGER ESPINOSA & JEFFREY STANZLER
The Michigan model for educational telecommunications: Tipping the iceberg 1110
ROGER ESPINOSA
Making the CMC process more visible through technological innovation 1111
JEFFREY STANZLER
Mentor issues: Examples from the International Poetry Guild 1112
DOUGLASS SCOTT
Teacher's role in the ICS model: Examples from middle schools 1113

SHORT PAPERS

ALAN AMORY
An institution strategy: Developments and examples 1114
DAVID ARNOLD
New information technologies and rural societies 1116
PATRICIA RYABY BACKER
Electronic portfolios as a mechanism for learning and student achievement 1119
MARIA BAKARDJIEVA & LINDA HARASIM
The discourse of online learning: Cognitive and interactive dimensions 1121
WILLIAM G. W. BARNES
After 400 multimedia projects... 1124
ROBERT E. BEASLEY
Using proximity matrices to identify predominant patterns of navigation through hypermedia knowledge spaces 1126
PATRICIA ALEJANDRA BEHAR & ANTONIO CARLOS DA ROCHA COSTA
Base models for organizing the logical-operatory analysis of cooperative computational environments 1129
ALFRED BENNEY
Jump-starting the use of technology in the humanities classroom 1131

Gunner Bergh & David Mighetto
The hyperlanguage project: A work-in-progress report 1134
Thomas A. Birk
Benchmarking distance education decision-making at conventional four-year college and universities in the United States 1136
Marie-Michele Boulet
The story behind the development of the television distance education course: Computer hardware and software components 1139
Jacqueline Bourdeau, Martine Chomienne, Jesus Vazquez-Abad, Barbara Wasson, & Laura Winer
Developing instructional design principles for collaborative telelearning 1141
Fred H. Bowers, James G. Wingate, Vonda Powell, Jaclyn Branner, Lucinda Brown, Yvette Daugherty & Terri Evans
Statistics via goal-based scenarios 1143
Kevin Brady & Claude Toth
Developing a multimedia template for classroom learning of history and geography 1145
Stephen P. Braham & Nathalie Sinclair
Activated scientific knowledge and education 1148
Jerry Brown, John Didier & Edit Pena
A CD-ROM based resource kit for instructors and practitioners in the developing world: Managing the implementation of development projects 1152
Wren M. Bump
Learning by doing—teaching hypermedia hyperactively 1154
Christopher Burnett
Crumbling walls: Hypermedia sketchbooks in art education 1156
Andrew Burrell
A study into the future use of synchronous and asychronous technologies in the distance ESL education area with an emphasis on collaborative learning 1159
Patricia A. Carlson, Dan Thompson, John Hornyak & Laurie Ruberg
The integrator: A tool for teaching strategy acquisition in scientific inquiry 1161
Terry Chandler
The virtual learning center: Distance education on the Web 1163
George Chapman & Barry Grant
APOLLO 2000: An Internet-based interactive, multimedia, multiplayer, virtual reality program applied to science/humanities education 1165
Guey-Fa Chiou
Intranet learning environment for junior high school's computer course 1167
S. Youn Chyung, Judi L. Repman, William Y. Lan, & Donald J. Winiecki
Effectiveness of an intelligently adaptive CAI environment with cognitive apprenticeship of self-regulated learning skills 1169
Bin Cui
HyperClock: A concept of a new navigational tool based on Hyper-G 1171
T. Dakin, L-E. Ljung, A. Gurunlian, I. Ingelaere, & S. Stromberg
LINES: Learning and Information Support Networks in Europe for SOCRATES 1173
Tilak de Alwis
The power of animation in visualizing mathematics 1175
Gideon de V de Kock & Marinda Taljiard
Computerized African language learning 1177
A.F. Dean
Techknowledge transfer and CMC in higher education in Australia 1179
A.F. Dean
iDEANet - An exploration of poly-media 1183
S. Demetriadis, A. Pomportsis, G. Bleris & O. Valassiades
Design issues for hypermedia educational environments: The case of "ISTOS" 1186
Thomas A. Drazdowski
Multimedia in teacher education: A small college approach 1188

M. Peta Dunkley & Norman M. Smith
Organisational factors influencing online real-time tele-events 1190
William J. Egnatoff & Mark Danby
Computer conferencing to support school-university collaboration in teacher education — A case study 1192
Joni Falk, Gloria Jacobs, Bridget Mooney, Jack Lochhead,
Brian Drayton & Jon Obuchowski
Strategies for promoting communication between diverse teacher enhancement communities 1194
Laura Farinetti & Anna Rosa Scarafiotti
Hypermedia and learning goals 1196
Joan Ferres & Antonio R. Bartolome
New media enhanced education: More than to add new resources 1198
Colleen Finegan-Stoll, Ronald Helms & Bonnie Mathies
Educational technology and preservice teachers 1201
Jane Fritz
Learning proof techniques through visualization 1204
A. M. Fryatt & D. A. Gregg
The Nechako Electronic Busing Program: Distance education options for K-10 students 1206
Jayne Gackenbach
Assignment responses as a function of ON-line vs. classroom presentations of a course on dreams . 1209
Lucie Gagnon & Sonia Allard
SAMI (C-L2): Development and evaluation of a multimedia cooperative learning system 1211
Algis Garliauskas
Neuroinformatics at the secondary and post-secondary levels of education in Lithuania 1213
Gregory Patrick Garvey
Reverse engineering the computer graphics animation and multi-media job market: A fine arts curriculum for the digital age 1214
Clark Germann & Sharon Siverts
The role of educational technology in the Ukraine and the Philippines: Two case studies 1216
Kevin A. Gluck, Marsha C. Lovett, John R. Anderson & Joon W. Park
Learning about learning from Stat Lady 1218
Dave Goforth
Peitho: A support tool for learning critical thinking 1220
Anatoliy S. Gordonov & Michael E. Kress
Educational analog/digital video networks 1222
Jennifer Hall & John Oates
Proficiency and practice with observation: A child development theory and methods tool 1224
Mary Hammond & Susan Bell
Business skills online: Strategies for the electronic environment 1226
Mary Hammond, Maureen Malcolm, Enid McCauley & Cleo Reece
First nations distance education: A collaborative approach with the first nations of B.C. and the Open Learning Agency 1228
Charles H. Hawkins, Jr., Kent L. Gustafson, & Tom Nielsen
Return on Investment (ROI) for Electronic Performance Support Systems: A Case Study 1230
Toshihiro Hayashi, Yukuo Hayashida & Yoneo Yano
Attractiveness in video game 1232
Jeff Hill, Bob Buerger & Jim Herstine
Implications for virtual reality in natural resource recreation management curricula 1234
S.J. Hill, N.J. Fiddian, W.A. Gray & D. Morrey
In search of integrated education: A knowledge management approach to the design and development of clinical computer based instruction 1236
Peter S. Ho & Geoff Whale
A multimedia system for reinforcing computer programming skills 1239
Peter Holt
A distance learning system for computing & information systems students 1243
Dave Hurley
Synchronized audio/visual tutorial modules on the Web 1246

DAVID IBSEN
Experimental collaborative information networks 1248
ESTHER JAVETZ
Quality in distance education 1250
BORKA JERMAN-BLAZIC
Distance education project in a country with transition economy—experiences and lessons learned 1252
MINGMING JIANG & CARLA MESKILL
How are students working in an online course? 1255
BRADLEY F. JOHNSON
Making the transition between traditional and Web based course material 1257
LINDA JONES
Development of interactive, multimedia educational software for studying Native American cultual history and foreign languages. 1259
TRICIA JONES, PHILIP MYERS & ROGER ESPINOSA
The animal diversity Web 1261
INSUNG JUNG
Design of a virtual university in a Korean context 1263
YANG KAICHENG & HE KEKANG
An intelligent hypermedia teaching system for Chinese language learning in primary school 1265
SUSUMU KAKUTA, AKIHISA KAWANOBE, YASUHISA KATO & KATSUMI HOSOYA
Interactive 3-D physical-simulation environment in a virtual world 1267
MICHIKO KAYASHIMA
Cross-age tutoring as cognitive apprenticeship 1269
EDWARD J. KAZLAUSKAS, DIANE E. BAILEY, MAGED M. DESSOUKY, SUSHIL K. VERMA, SADASHIV ADIGA & GEORGE BEKEY
The development of a virtual factory teaching system 1271
WILLIAM KIRBY

Abstract: In this paper we describe an empirical study which aimed at analysing the processes involved in the authoring of hypermedia applications for education. The study consisted of interviewing either researchers or lecturers from the University of Southampton involved in the development of hypermedia applications for education. The issues addressed in the interviews were classified as either general or specialised and the study is part of a research project called SHAPE. The aim of SHAPE is to aid authors in the development of good quality large-scale applications for education.

1 Introduction

Hypermedia authoring has been a wide area of research and interest in the last few years. There are many ways in which the meaning of authoring can be understood and, consequently, many corresponding solutions offered to hypermedia authors.

Authoring can be considered a writing process [Nanard & Nanard, 95] and, in a similar way, involves the same processes used in writing: planning, translating and reviewing [Flower & Hayes, 80], [Hayes & Flower, 80]. Authoring in the large requires a lot of planning in order to develop reusable and maintainable applications [Ginige et al., 95]. And if authoring is applied to education the number of variables to analyse increases significantly.

2 The SHAPE Project

SHAPE is an acronym that stands for Southampton **H**ypermedia **A**uthoring **P**aradigm for **E**ducation. The aim of SHAPE is to aid authors in the development of good quality large-scale applications for education. In this sense, good quality means easy reuse and maintenance of information and also means that the authoring tool used influences positively the authoring process. The empirical study described in this paper is part of the SHAPE project and is aimed at analysing the processes involved in the authoring of hypermedia applications for education. Throughout this paper "author" means anyone who writes or composes a book or other literary work.

3 Methodology

The empirical study was conducted using interviews at the University of Southampton in 1996. The participants were either researchers or lecturers involved in the authoring of hypermedia applications for education and thirteen people volunteered. Nine authors were involved in all the development phases, from the design of the structural knowledge [Diekhoff, 83] for the domain and the authoring of nodes' contents to the interface design and application implementation. Three authors were involved only in the management of the development and one author was involved in the definition of the structural knowledge [Jonnassen, 93] and in the authoring of the contents of nodes. Some authors have been involved in the development of more than one application, which makes the number of applications used in our sample data (twenty) greater than the number of volunteers.

Nine applications were developed by authors who already had experience in the development of at least one hypermedia application for education. Six applications were developed by authors who had read about hypermedia but had no direct experience in the development of hypermedia applications and five applications were developed by authors who had no previous experience or knowledge about hypermedia. The number of small, medium and large applications, where we consider a medium size application to have a number of nodes between 100 and 500, was five, ten and five respectively. The domains used for the applications' content were Rheumatology, Cognitive Psychology, Sociology, Archaeology, Oceanography, Engineering, Physics, Geography and Biology.

The issues considered in the interviews were arranged into *general* and *specialised*.

The *general issues* addressed were:

- if there was a general method/methodology for the authoring of hypermedia applications for education.
- differences and similarities between the cognitive writing processes used in the development of hypermedia and non-hypermedia applications for education.
- if the links were considered essential when structuring the knowledge domain.
- the importance of representing the author's cognitive map [Diekhoff & Diekhoff, 82] in the structure of the application and if the learners needed to know it in advance.
- if the development could be divided into different phases and groups.
- if there were commonalties among the resources used.
- what was the most commonly used instructional approach.
- how the applications were introduced in the courses.
- if the authoring tool used influenced the interface design and the implementation of the application.

The *specialised issues* addressed were:

- differences between experienced and non-experienced authors concerning the approach used for authoring.
- the influence of the application's size on the approaches used by the authors.
- if there was a relationship between the authors' role and the authoring approach they've used.
- if authors considered context-dependent links as well as typed links important for conveying information to the learners.
- if authors structured the information using different levels of granularity.

4 Results and Discussion

4.1 Results for the General Issues

a) Was there a general method/methodology for the authoring of hypermedia applications for education ?

We cannot affirm that there was a general method/methodology if we consider the strict definitions of both words. But we can affirm that we found general guidelines. Among the applications, twelve were developed by authors who designed in the first place the structural knowledge for the domain and then looked for resources (references, images, videos, sound, etc.). Seven were developed by authors that alternated between the structural knowledge's design and the search for resources and only one was developed by authors that looked for resources before designing the structural knowledge.

Eight authors answered that there was not a common way that could be used to structure any domain. Three answered that it could be the same when considering the same domain and two answered that it could be the same for any domain. Twelve authors, almost the totality, answered that there was not *the best way* of structuring the domain, from the readers' point of view. These results were expected since the structure is influenced by many different variables such as the educational goals, the author's understanding of learning and teaching, the social as well as the cultural contexts in which the author is inserted, to mention some.

b) What are the differences and similarities between the cognitive writing processes used in the development of hypermedia and non-hypermedia applications for education ?

Seven authors used a top-down approach. Among these, four authors have already developed more than one application and only one out of these four used a different approach on the development of her first application. All the others used a top-down approach for the first and subsequent applications. The top-down approach was used in three different ways: subdividing the domain into different areas - two authors; using a Table of Contents - one author; and defining a hierarchy of concepts - four authors.

Six authors used a mixed approach. The mixed approach is also described as one of the possible mental processes commonly used [Hayes & Flower, 80], [Nanard & Nanard, 95].

Only one author used a bottom-up approach for the first application developed. The bottom-up application was small and at that time the author had only read about hypermedia. For the development of hand-crafted applications little planning is required since all of the information can be kept in short-term memory.

An interesting point to mention is that *all the large applications* (four) were developed using a top-down approach. Among these, three were developed by non-experienced hypermedia authors - two with the role of managers and one with the role of developing everything. One large application was developed by an experienced author whose role was to develop everything.

c) Were the links *essential* when structuring the knowledge domain?

Ten authors, almost the totality, answered that the link information was **not** essential when structuring the knowledge domain. Among these, half had already developed at least one hypermedia application for education beforehand and four were the authors of the four large applications considered in our sample data.

Two authors answered that the links were essential and one answered that it was dependent on the educational goals.

This result reflects that the development of a hypermedia application should neither be constrained by the links available nor by the "hypermedia style", as Stevan Harnad [1] pointed out (personal communication): "You can improve the discursive text by adding hypertext links, but to make the discursive text written with hypertext in mind, forcing it into hypertext moulder of any kind, is going to make it worse. At least, the good ones".

d) Is it important to represent the author's cognitive map in the structure of the application and do learners need to know it in advance?

Eight authors, almost two-thirds of the sample used, answered that it is important to represent in the structure of the hypermedia application the author's cognitive map for the knowledge domain. Three answered that it was not important and two answered that it was dependent on the educational goals. Nine authors, more than two-thirds of the sample used, answered that learners needed to know in advance the author's cognitive map for the knowledge domain. Three answered that it was not necessary and one answered that it was dependent on the educational goals.

e) Could the development be divided into different phases and groups?

Eight authors answered that the interface design, the structural knowledge design and the authoring of the nodes' contents can be done separately. Among these, six answered that it is possible if there was constant interaction among the groups and two answered that it was possible even if the interaction occurred only at the end of the development.

Two of the three authors involved in the development of large applications answered that the development could be split into different phases and groups. Four authors answered that the structural knowledge design and the authoring of the nodes' contents should be done by the same group.

Interaction was the word mentioned by eight authors, two-thirds of the sample used. It could happen at the end or be a continuing process, but it should happen. The results were very important since large-scale hypermedia applications can very rarely be developed entirely by the same group. It may involve the sharing of tasks among different groups, departments, universities and even countries.

---

[1] Professor Stevan Harnard is the Director of the Cognitive Sciences Centre at the University of Southampton

763

f) If there were commonalties among the resources used?

The resources used and the number of authors that used each one [Tab. 1] reflect the kind of applications being developed at the University.

Resources	Authors	Resources	Authors	Resources	Authors
Text	13	Glossary	3	Summative assessment	1
Images	9	Databases	2	Thesaurus	1
Keywords	6	Dictionary	2	Index	1
Different SW for the interface	6	Simulation	2	Tutorial for beginners	1
Multiple-choice exercises	5	E-mail	2	Abstracts from papers	1
Video	5	Animation	1	Biographies	1
Web URLs	5	Archives	1	Spreadsheet	1
Search by Content	4	Quizzes	1	Graphic Tool	1
Diagrams	3	Tests	1		1

Table 1 - Resources used

g) What was the most commonly used instructional approach?

Eleven applications, more than a half, were developed using problem-solving as the instructional approach. Seven used an exploratory/research approach and two used drill and practice. It is important to mention that among the four authors involved in the development of applications using an exploratory approach, three have answered that the author's cognitive map should be present in the structure of the application and that learners should know this cognitive map in advance. The results show that hypermedia applications for education are more than just encyclopaedias where the students have to explore freely the contents in order to learn. To develop a hypermedia application as encyclopaedia is to forget the existence of the context in which learning takes place. And the context is one of the fundamental tools for education [Whalley, 93], [Simon, 95].

h) How were the applications introduced in the courses?

Sixteen applications, four-fifths of the total number of applications, were used to complement classes, two were used as a substitute and two were used either to complement classes or as a substitute for classes. This analysis shows that authors are not developing hypermedia applications to substitute their classes. The applications are mostly being used to complement classes, so they can enhance learning. The authors that developed applications to be used as a complement to classes had either of two objectives in mind: the application be used in a way to reinforce the knowledge learnt during formal classes or to allow learners to practice the concepts presented in the classes.

i) Did the authoring tool used influence the interface design and the implementation of the application ?

Our objective was not to evaluate or even compare the authoring tools used but to find out generally the influence of the authoring tool on the design of the interface and implementation. All the authors of our sample either used the Web or Microcosm [Davis et al., 92] as an authoring tool. Some authors used a front-end software (Assymetrix ToolBook or Microsoft Visual Basic) on top of Microcosm to design the interface. The only issues considered [Tab. 2] were the ones mentioned by the authors, since there were no suggestions provided.

Issues	Authors	Issues	Authors
flexible to incorporate other software	2	restrictive concerning the interface	4
good searching mechanism	1	no flexibility	4
flexible in general	4		

Table 2 - The general influence of the authoring tool

BEST COPY AVAILABLE

4.2 Results for the Specialised Issues

a) Were there differences between experienced and non-experienced authors concerning the approach used for authoring ?

All the four authors that did not have any previous experience in the development of hypermedia applications used a top-down approach.

Among the authors that have only read about hypermedia before developing their first application, two used a top-down approach, one used a bottom-up approach and three used a mixed one.

Among the seven authors that have developed at least one hypermedia application for education three used a top-down approach and four used a mixed one.

The top-down approach was chosen by the majority of authors, independently of their role.

b) Did the application's size influence on the approaches used by authors?

All the large applications, four in total, were developed with a top-down approach to authoring.

Among the ten medium size applications developed, half were developed with a top-down approach and the other half with a mixed approach.

Among the six small applications, half were developed with a top-down approach, two with a mixed approach and only one with a bottom-up approach.

The bottom-up approach was used only once, considering the twenty applications of our data sample. Almost all the applications were developed using either a top-down or a mixed approach. This result shows that planning is fundamental for the development of applications, either in the beginning of the development or as an iterative process.

c) Was there a relationship between the author's role and the authoring approach used?

We did not find a significant relationship since in all situations the majority have chosen either a top-down approach or a mixed one.

d) Did authors structure the information using different levels of granularity ?

All the authors used different levels of granularity for the information they structured. This result shows that it is fundamental to impose some levels of abstraction in order to help the learner.

e) Did authors consider context-dependent links as well as typed links important for conveying information to the learners ?

Nine authors, more than half of the sample, considered it important to use context-dependent links. Four did not consider contextual links important.

Nine authors, more than half of the sample, considered typed links important to conveying information to the learner. One author answered that it was dependent on the kind of application. Three authors did not consider typed links important.

5 Conclusions

Hypermedia authoring for education is a very complex task. Authors have to consider many different variables, all important and interrelated: the design of the domain's structural knowledge, the instructional theory to use, the educational goals, the learning theory upon which the instructional theory is based, any instructional design guidelines, how the application will be used in the course, the hypermedia tool available for the interface design and implementation, the interface design, which links to define, and how to organise the information for novice as well as experienced learners.

The main results are:

- It is important to keep the context when developing applications with educational purposes
- The top-down approach is widely used as a way of planning, organising thoughts and structuring the knowledge
- Authors' cognitive writing processes remain the same when considering hypermedia authorship
- The authoring tool is a key point in helping the authoring process, specially when considering large-scale applications
- Authors, at least at the University, use hypermedia applications as a complement to their classes.
- Cognitive maps, contextual links and typed links are important for knowledge structuring and for Conveying local as well as global coherence to learners

Our purpose is to help authors in the development of good quality hypermedia applications for education. To do so we are undertaking a research project called SHAPE. The empirical study presented in this paper is one of the sub-products of the project and is aimed at investigating the processes involved in the authoring of hypermedia applications for education.

Categories of Computer Use and Their Relation With Attitude Toward Computers

Ananda Mitra
Department of Communication
Wake Forest University
USA
ananda@wfu.edu

Abstract: This paper reports the relationship between computer use and attitudes toward computers. The results from three surveys demonstrate that there are several categories of computer use among students and their attitudes towards computers is related to the categories of use. These differences and relations have possible far reaching implications for institutions which are planning widespread computer implementation in teaching. If the students have a negative attitude towards computer use, it could impact their level of use of computers. That, in turn, can have an impact on learning and the way the learning process changes with the adaptation of computers.

Introduction

With the increasing use of technology in education and training it is becoming important to assess the relationship between attitudes towards computers and the level of usage of computers. In the past these questions were relatively standardized and both attitudes and usage could be measured with standardized tools. Particularly in the case of attitude towards computers, tools such as the Computer Attitude Measure (Kay, 1989) and Attitudes Towards Computer Usage Scale (Popovich , et., al. 1987) included a set of standardized questions that measured how users felt about computers. However, with the increasing sophistication of computers, and early adaptation in schools both the patterns of usage and attitudes are bound to change. In the past, usage was measured primarily around the issues of temporality, instruction and applications. In the case of temporality, the focus was on measuring the length of time an user would have used computers. For instance, relations were drawn between the length of usage and attitudes just as differences in opinion were studied between fresh users and experienced users (see, e.g., Gustafson, 1992; Okebukola, et. al, 1992). In a similar fashion the issue of attitude and its relation to instruction has been examined as well. Instruction has most often been defined as the amount of formal training an user has received in the use of computers. As in the case of new users and experienced users, the amount of training has often been different leading to differences in attitudes and perceptions. Often instruction and application coalesce together where researchers would combine the component of instruction with application which refers to the breadth of computer usage in terms of the software the user executes on the computer. For instance, specific software applications have been studied and relations have been drawn between specific applications and resulting attitudes (see, e.g., Wu and Morgan, 1989; Chen, 1985; Kay, 1992; Igbaria et., al., 1995b).

Based on the past research what becomes clear is that there has been an interest in the assessment of the relation between computer usage and attitude towards computers. As pointed out by Kay (1989) this is based on fundamental assumptions about attitudes, beliefs and behaviors as suggested by Ajzen and Fishbein (1980) in their seminal work on the relationship between attitudes and the prediction of behavior. Consequently there have emerged several attitude measurement scales and procedures (see, e.g., Richards 1986; Kay 1992; Kay 1989; Abler, 1985; Loyd and Loyd, 1985; Pinto, 1985; Bannon, 1985). There has, however, been little agreement about any standardized scale that can be used in a generalizable fashion. We argue that is the case because of increasing fragmentation of computer use, and the resulting differences in the ways in which computers are being used. It is not only difficult to develop a standardized scale but also difficult to categorize usage on the basis of length of use, training and application-centered analysis alone.

In this paper we argue that it is important to consider the variety of uses that potential and existing computer users can have, particularly in the educational setting of an undergraduate college. However, that use is not measured in terms of experience, training or specific applications. In stead, use is measured in terms of the specific tasks that the computer is used for. Further, this paper explores the relationship between the specific task based use of computers and attitudes towards computers. There are thus two key exploratory research questions that are raised:

1. What are the specific tasks for which computers are used in undergraduate education?
2. What is the relationship between specific task-based use and attitude towards computers?

Methods

Procedure

The survey was administered during the registration period to all the students enrolled at the University. There was only one attempt at collecting the data. The questionnaire used for the survey was the product of a set of focus groups with members of the population. These focus groups yielded valuable information about the key issues facing the students of the specific University which was in the initial stages of a massive reorganization of its computer infrastructure that included a long-term contract with a major international computer company that would be providing all students at the University with a mobile computer. This survey, a part of a longitudinal study, was conducted a year before the standardized computers were to be made available to the students. Participation in the survey was voluntary and an overall response rate of 38% was obtained.

The questionnaire was four pages long with several sections. The first of these sections dealt with attitude towards computers. There were a total of 24 attitude items of which several dealt with the specific aspects of the computerization initiative taken by the University. There were five items that dealt with general attitudes towards computer use. The attitude measures all consisted of five-point Lickert-type items (Strongly Agree, Agree, Not Sure, Disagree, Strongly Disagree). In a similar way, the usage questions consisted of 11 four-point Lickert-type items (Very Frequently, Frequently, Infrequently, Never). Other subscales included the measurement of the factors that affect the teaching effectiveness of computers, frequent communication activities (e.g., face to face communication with teacher, etc.) of the students, and demographics. The latter was made up of self-perception of computer expertise, gender, school year, income, ethnicity, and citizenship status.

Sample

The entire population of the University were given questionnaires and at the end of the registration period a total of 1,444 surveys were returned (52.6% male, 47.3% female), ranging in school year from freshman to senior with 32.1% being freshmen, 25.3% being sophomores, 20.3% being juniors and 22.3% being seniors. All the major disciplines at the University were represented with 25% claiming a science or math related major, 28.3% claiming a liberal arts or social science related major, 14.7% claiming a business major and 2.5% claiming a fine arts related major. The average household income of the students was reported in the range of $81K and above with 37.4% of the respondents reporting an average household income of $101K and above. Finally, 89.4% of the respondents were white with 6.6% being African-American and the remaining 4% being distributed between Asians (2.4%) and other ethnicities.

Research Design and Method of Analysis

The means, standard deviations and internal reliability coefficients were determined for the five item subscale for the general attitude towards computers. A principal component factor analysis, followed by varimax rotation of the factor solution was used to determine the four primary uses of computers. This was followed by a re-coding of the usage measure into dichotomous (high and low) variables. Students t-tests were performed along with tests of homogeneity of variance of groups to test for significant difference in attitude between high and low users. Finally, linear regression analysis was conducted with levels of usage as dependent variables and attitude as independent variables to test for the relationship between attitudes and the predicting power of attitude measures.

Results

The means of the attitude measurement scales fluctuated from 2.80 to 3.47. The standard deviations for individual attitude items ranged from 0.98 to 1.21 (Table 1). The alpha coefficient for the attitude scale made up of the five attitude items was 0.69. The mean of the usage measures varied from 3.56 to 1.54 with standard deviations ranging from 0.68 to 1.26 (Table 2). The alpha coefficients for the three subscales of task based Network use, non-task Network use, data management and mathematical computing were 0.57, 0.73, 0.67 and 0.71 respectively.

Table 1: Mean and Standard Deviation for Attitude Towards Computers Measure (N=1,444)

Item	Mean	S.D.
1. Increased use of technology in teaching makes learning easier	3.47	0.98
2. The introduction of computers to teaching is too rapid	2.90	1.02
3. I feel comfortable using computers	3.57	1.12
4. I have a certain apprehension about computer use	2.80	1.21
5. Computers in teaching makes the learning process too impersonal	3.17	1.04

Table 2: Mean and Standard Deviation for Usage Measure with 1 = Never, 4= Very Frequently (N=1,444)

Item	Mean	S.D.
1. Using the Internet to get information	2.83	1.02
2. e-mail with friends	3.40	0.90
3. e-mail with family	2.31	1.26
4. e-mail with classmates	2.57	1.09
5. e-mail with teachers	2.16	0.92
6. e-mail with student organizations	1.79	0.95
7. Statistical computing	1.54	0.76
8. Mathematical computing	1.66	0.85
9. Spreadsheet	1.60	0.85
10. Database management	1.56	0.81
11. Word-processing	3.56	0.68

The principal component factor analysis produced a four factor solution accounting for 68.7% of the total variance. The varimax rotated factor loadings greater then 0.40 are shown in Table 3. Each of the four usage subscales produced a relatively distinct and cohesive group.

Table 3: Varimax Rotated Factor Loadings for Usage Measures

Subscale	Item	Factor 1	Factor 2	Factor 3	Factor 4
Net use for non-task activity					
	Using the Internet to get information	0.48			
	e-mail with friends	0.81			
	e-mail with family	0.78			
	e-mail with classmates	0.59			
Net use for task activity					
	e-mail with teachers		0.67		
	e-mail with student orgs.		0.83		
Mathematical Computing					
	Statistical Computing			0.77	
	Mathematical Computing			0.88	
Data Management					
	Spreadsheet				0.78
	Databases				0.84

The pooled variance t-tests with low and high users in each of the five categories of usage yielded significant differences between the means of each of the attitude measures at $p < 0.001$. The means for each group are shown in Table 4. The cell size for each group is also reported in the table. Given the unequal cell sizes, tests of homogeneity of variance were conducted for all the t-tests and in none of the cases were the variances found to be significantly different.

Table 4: Difference between Attitude Item Means Based on Low and High Usage (numbers in parenthesis indicate N)

	Net 1	Net 1	Net 2	Net 2	Math	Math	Data	Data
	Lo	Hi	Lo	Hi	Lo	Hi	Lo	Hi
1	3.38(947)	3.66(435)	3.15(303)	3.56(1066)	3.42(1176)	3.75(198)	3.42(1150)	3.73(230)
2	3.02(949)	3.25(436)	2.81(303)	3.18(1070)	3.06(1180)	3.36(198)	3.05(1154)	3.33(230)
3	3.44(947)	3.83(435)	3.00(300)	3.73(1070)	3.49(1179)	4.01(196)	3.45(1151)	4.11(230)
4	3.11(947)	3.37(431)	2.73(298)	3.33(1068)	3.11 (1176)	3.64 (195)	3.09 (1151)	3.71 (230)
5	2.78(950)	2.94(433)	2.52(303)	2.92(1068)	2.78 (1181)	3.12 (195)	2.77 (1154)	3.14 (228)

Finally, all correlation between each of the attitude scales, the summed attitude scale and the usage scales were found to be positive and significant ($p<0.001$). The correlation coefficients are shown in Table 5.

Table 5: Correlation between attitude measures and usage measures

	WP	Data management	Mathematical	Net for Non-Task	Net for task
Multiple R for all attitude items	0.17	0.25	0.20	0.31	0.19
Item 1	0.10	0.17	0.15	0.23	0.15
Item 2	0.11	0.17	0.13	0.22	0.14
Item 3	0.20	0.29	0.23	0.36	0.21
Item 4	0.14	0.24	0.19	0.25	0.15
Item 5	0.11	0.17	0.15	0.19	0.10

Discussion

The purpose of the analysis of the survey data was to explore the different modalities of computer use and then seek any relationships that might exist between the categories of use and attitude towards computers. The results suggest that there are distinct categories of use as well as significant relationships between categories of use and attitudes. The sample for the study was sufficiently large and diverse to lend statistical merit to the results. The item standard deviations were relatively consistent for both the attitude and the usage measures. Furthermore, the high alpha coefficients for the attitude measures as well as the usage subscales suggest high internal reliability.

First, it is clear that there are four specific areas of computer use for different tasks. As demonstrated by the factor analysis, college students use computers for five main tasks. This suggests that when considering the concept of "usage" it is necessary to distinguish between different kinds of use. Secondly, this is all the more important since the findings suggest that there are significant differences in attitude of the high and low users in all categories of use. In general, low users of computers tend to have a more negative attitude towards computers. However, the difference is most marked in the case of the items "I feel comfortable using computers" and "I have a certain apprehension about computer use." For instance, the difference in attitude means on the first item was 0.73 between the low and high users of the Network for task purposes. Similarly there was a difference of 0.66 units for the same item between low and high users of data management programs. On the other hand, the difference on that measure was least (0.39 units) for low and high users of the Net for non-task purposes. This would suggest that students are often forced to use the computer for task purposes even when they might have a negative attitude towards computer use. Conversely, those students who have a positive attitude tend to use the computers more for task purposes. This is further borne out by the low correlation between summed attitude items and computer use for task purposes. This indicates that the variance in computer use for task purposes is minimally explained by attitude and is perhaps better explained by the fact that students are forced to use computers in some classes. This could suggest that students use computers for task purposes because they are forced to do so and not because they are interested in computers. On the other hand, the higher correlation ($r=0.31$) between summed attitude items and Net use for non-task purposes suggests that those who have a positive attitude towards computers readily use it for non-task purposes.

Conclusion

Based on the results of the 1,444 surveys it is clear that there are several categories of computer use among students and their attitudes towards computers is related to the categories of use. These differences and relations have possible far reaching implications for institutions which are planning widespread computer implementation in teaching. If the students have a negative attitude towards computer use, it could impact their level of use of computers. That, in turn, can have an impact on learning and the way the learning process changes with the adaptation of computers. While it has been known that there is a relationship between computer use and attitudes towards computers, the results reported here demonstrate that computer use is not a monolithic and singular construct. Indeed it is a multi-dimensional element and there are different relationships between categories of use and attitude towards computers. These different relations need to be considered when computers are used in teaching.

Abstract: This work describes how hypermedia and network technology can contribute to creating a Distributed Open Learning/ Teaching Environment. In particular, we present a case study of teaching natural sciences in primary schools with a didactic itinerary, called 'The Mammals', which was designed and developed by the Natural History Museum of the University of Pisa. We outline the psycho-pedagogical basis of the project, along with organisational aspects, operating tools, project criteria, and the electronic and computer support.

1 Introduction

The Natural History Museum of the University of Pisa (henceforth, the Museum) has long been interested in didactic problems, and in the role museums can have in education on a local scale [Boni. 91, Fran. 91, Zuff. 91]. The Museum has been particularly interested in designing didactic itineraries, such as Mammals and Amphibians, in order to enhance the intellectual development of primary school children. In fact, the Museum has recently planned to install a computer network (EnviNet Project, [Sbrana.95]), promoted by the local authorities and aimed at building a network of centres for environmental education within Tuscany. Our work has been to provide hypermedial and network communication support for this Distributed Open Learning/ Teaching Environment, in which relevant didactic concepts could be integrated and expanded through extra-mural visits, presentations and experiences with other museums, natural parks, laboratories, scientific observatories, etc. Within the EnviNet project a laboratory on environmental education will be created at the Centro di Documentazione e Ricerca Educativa of the Provincial Administration of Pisa plus four other related centres (all connected by the same computer network).

Section 2 outlines one particular didactic itinerary, the Mammals, which was designed by the Museum for primary schools, and which fits into the general framework of museum/school integration in natural sciences and environmental education. Section 3 analyses the rationale behind the project for introducing computer and electronic support for teaching, and details some aspects of the solutions that have been implemented.

2 The Mammals - A didactic itinerary

Below we summarize the fundamental psycho-pedagogical and structural aspects of the Mammals itinerary, which was designed by two of the authors of the present paper, Berni and Zuffi, who have primary school teaching experience alongside research in zoology at the Museum. For further details see [Berni.96].

2 a Psycho-pedagogical basis of the itinerary

The main aim was to help children to understand, in this case through observing the skeletons of 10 species of mammals, the relationship between the variances found and the functional adaptation needs to the environment. The starting and reference point is a human skeleton, ie the skeleton of the children themselves. This is used to show the children how they perceive it and how they schematize such perceptions. The children then compare this human skeleton with the skeletons of the mammals, again on a perception/sensory level. This enables them to hypothesize on why changes have come about in the structure of the various mammals.

Understanding how and why mammals diversify and are transformed as a reaction to the environment, helps children to focus on natural processes (above all in the animal world), and offers a dynamic perspective on the interactions between life environments and the physical characteristics of the organisms.

The itinerary is based on three main factors: (i) establish what the children already know; (ii) limit the work to mammals, specifically those which can be compared to a basic skeleton structure (10 animals); (iii) get children to give plausible explanations for these variations in terms of function, and adaptation to the environment, without any quantified time references.

This rationale entails radically altering the traditional approach to museums, where visiting classes are accompanied by an 'expert' who imparts knowledge, often in overly technical language, with questions being left to the end. Instead in our case, it is the children who ask the questions from the outset, the role of the expert being to guide the children in their discovery of the distinctive properties of the various mammals.

The underlying concepts of this didactic itinerary derive (i) from Piaget's ideas [Piaget. 66, 73] on the formation of thought in children, and later studies on its 'magic' tendency [Donald.79], (ii) from research into conceptual maps in children's thought [Pontec.86], and (iii) from studies on preconceived ideas that may condition learning [AA.VV.85,.89, Berni.89]. A child's preconceived ideas on any subject covered in a syllabus must be known, so that teachers will ask the 'right' questions. In answering, the child will objectify his/her knowledge and will thus interact with the subject of learning. This interaction should modify any erroneous preconceptions, thus leading to a correct, stable, and lasting knowledge. When children are free to test out their own ideas and to compare these ideas with their companions they will be able to build their own social knowledge. In this case the teacher takes on a new role as stimulator and mediator. Back in 1954 Dewey had already envisioned this as the role of the teacher in an 'active school' [Dewey.54], even though this was only an intuition that was not objectified by the psychological processes with which child learning takes place.

2 b Didactic structure

Below is the framework of the activities of the didactic itinerary [Berni 96].

Objective:	*distinguish between mammals and non mammals*
Activity	children (i) divide pictures of animals into sets of mammals and non mammals using their own reasoning; (ii) compare criteria underlying their selection; (iii) if necessary, integrate their knowledge with simple information
Objective:	*find out which animals were really recognised by the children*
Activity	children (i) write a free list of names of the animals (mammals and others) that they claim to know; after some time, (ii) teacher gives the list back to the childs, and (iii) get them to write down what each animal eats and where it lives
Objective:	*investigate what perception children have of their own skeleton within the body scheme*
Activity	children (i) do a spontaneous and free drawing (without giving them any clues); (ii) get children to touch their body, telling them verbally which specific parts to touch, children now (iii) do a spontaneous and free drawing; (iv) use physical exercises so that children get a better perception of how their bodies are articulated; (v) children draw a skeleton, within the outline of a human body, on the basis of knowledge learned in the above physical exercises

Stage 1: External exploration Visit to the Natural History Museum for an initial contact with the 10 animals and some first hypotheses on changes and variations in their structure.

Stage 2: Internal exploration Children's knowledge of around 10 animals is compared to form the basis of Venn and Carrol diagrams founded on a 'similar-different' relationship. Reproduction, behaviour with offspring, nutrition, and habitat are considered especially in terms of internal structure vs external coating (ie the relationship on which the Museum is organised).

Stage 3: Cognition Children fill in three worksheets regarding the animals. The first sheet is filled in either individually or in pairs, and uses questions to guide children in observing physical and functional characteristics. The second sheet is read collectively, and gives information on the animals habits, habitat etc.; children can make comments and additions at will.

Stage 4: Revision Continuous revision using diagrams on the basis of new information on the animals.

Stage 5: Control Second visit to the same sections of the museum. Children meet with expert who gives information, settles curiosities, answers questions, and resolves any problems that came up in the first visit. The relationship between expert and visitor is traditional; this is a control stage since from the type of questions that the children ask, their level of attention, motivation and interaction can be assessed. Teachers should be arousing curiosity without answering the resulting questions.

Stage 6: Verification Children complete five worksheets: 1) children separate mammals from non mammals; 2) from a given number of possibilities, children identify the characteristics of a mammal's skeleton, and freely describe the behaviour of mammals towards their offspring; 3) children distinguish a mammal's skeleton from a non mammal's, giving explanations; 4) children locate some mammals, on the basis of their habitat, in some Carrol diagrams (cfr. [Rinaldi.85]); 5) for the 10 given animals, children identify what has changed in the internal/external structure and give plausible hypotheses on the reasons for such changes.

3 Project analyses and choices

This section outlines the rationale behind the project, for further details see [Berni.96].

3.1 Network Communication Support

In the Introduction we stressed the opportunities for contact enabled by having a Distributed Open Learning/ Teaching Environment which can be exploited by schools. On the other hand, in Section 2a, we also noted that the main features of the Mammals itinerary significantly alter the traditional roles of visitor and expert in a museum. This 'discovery' concept can already be seen in the preparatory stage before the first visit, when teachers limit themselves to a stimulator-mediator role. It is then furthered during the visits, particularly during the first when there is no expert present. Yet, at the same time, teachers have to deal with the fact that their own role has been radically redefined, and they too, to some extent, go on their own voyage of discovery. This naturally conditions how the itinerary should be organised, and what teacher support should be given, both in terms of the original didactic project and in terms of hypermedia and new network communication support tools.

The procedure in the original project

In the original didactic project there is a preliminary meeting between the authors of the project itself (Berni - Zuffi) and the teachers that are interested in testing it out in class. The psycho-pedagogic importance is outlined, along with the goals, methodology, activities scheduled, and the cognitive aspects relating to the biological world via an analysis of the morpho-functional differences of the mammal species under consideration.

At further meetings, teachers are given support for adapting the project to their class syllabus, and for going into cognitive aspects regarding animals. They are also helped in assessing and quantifying the data that emerge from the children's activities. Information and materials regarding the itinerary are exchanged, and teachers are encouraged to take children to see the animals they are studying in their natural habitat. Particular care is taken in preparing teachers for the first visit to the museum (when there is no expert present), in terms of what role the teacher should play and what questions the children should be asked, alongside practical information about where and how the animals are displayed in the museum.

The new procedure using network communication and hypermedia tools

Most of the initial preparation work before the visits to the museum can be based on hypermedia support and interactive exchange over the Internet. This includes most of the information, explanation and preparation phases of the teachers, leaving direct contact only to essential aspects. In fact, the Museum is planning to set up its own www site with the usual services (e.mail, WWW, FTP, Gopher etc) alongside the availability of some stations with external ISDN/H.320 connections, so that an A/V point-to-point communication environment can be made with similarly equipped stations in schools [MultiLab.95], via interactive telematic functions (ITF). Below is a brief summary; see [Contat.93] for further details.

Some examples of essential Interactive Telematic Functions (ITF)

audio talk	via phone talk directly to the person you're connected with (hereafter User 2)
video talk	see User 2
whiteboard	share your screen with User 2, and draw, call up images etc
shared applications	share applications in real time, allow User 2 to use applications in execution on your station, specifying which ones can be used. For example, User 2 can write documents on a word processor that is only available at your station.

These functions can be used by museum staff to interact with teachers in the organisation of didactic activities and class visits. In particular, for: (i) selecting didactic itineraries and preparing visits for particular users, eg schools, classes, environmental groups, nature club groups; (ii) preparing visits, plus carrying out the visits themselves, which as we have already mentioned, may be 'discoveries' for the teacher/group organiser; (iii) processing materials arising from the visit, such as producing reports, drawings (or in the case of extensions to middle and high schools), student to student interactive collaboration via the Internet. See [Berni.96] for primary school experiences with the Natural History Museum of Pisa, and [Carafa.96]) for middle and high schools.

This multi tool and multimedia solution saves considerably on time and organising loads. It also leads to greater autonomy, flexibility and operating efficiency both on the part of teachers and museum staff.

3.2 Hypermedia Support

When designing and developing the hypermedia support, we drew on the experience from the world of the environmental and cultural assets and also on various didactic applications developed at the Computer Science Department of the University of Pisa [Albe.95], in particular with reference to education on the environment [Lagana.95]. We organised this support into three sections: Tutorial, Mammals, and Worksheet Collection. These sections are strongly connected and integrated in their communication and hypermedia functionalities.

3.2a Tutorial This hypermedia is used to acquire knowledge on the various parts of the Project, aims and methodology; and to display the activities scheduled for the students, thus facilitating an intuitive and exemplification approach to the original project. This can be reduced to a few significant pages that can be easily accessed and read directly on the Internet. This section is for informing teachers, and for museum experts to spread information.

3.2b Mammals This is the most important section since it supplies the main support for the didactic project as a whole, and it resolves the interactions between the three main entities involved (Provincial Administration, Museum, and Schools). It is fully computerized and is primarily intended for schools, who can not only carry out didactic activities but also send and receive data and results. It can also be supplied to the Museum, where it should only be used for reception and to support interactions between all three components. Teachers can exclude or add animal worksheets. Schools with the same application can communicate with each other and exchange worksheets, images, comments, etc. Teachers can also file activities carried out by their students, which they can then consult, thus facilitating any assessment or quantification of such data.

3.2c Worksheet Collection This section is for collecting data on how the itinerary is going. Verification can be on two subjects:

1) children - directly on the their level of learning, via the completion of worksheets that establish the base knowledge on certain subjects (initial test) and then the worksheets relating to the contents and methodologies adopted during the execution of this didactic unit (final test);

2) teachers - via a questionnaire which finds out the level of satisfaction with the project, with some notes on changes that could be made to make the project itself more functional, with discussion and comparison of any modifications/customizations made in class.

The Museum already has data from various verification sources to assess the progress of the didactic activities. The data on pupil activities are collected in table form. The section on Worksheet Collection is used by the Museum and by the Provincial Administration, and supports School - Museum & School - Provincial Administration interactions. In that particular case, tables with students' marks are exchanged.

3.3 Detailed description of hypermedia support

When choosing the system to develop the hypermedia support our main criteria were simplicity, interactiveness, and diffusion in the school environment in order to facilitate use and so that teachers could easily make their own modification. We thus used a PC/Windows environment, equipped with a Multimedia Toolbook, version 3.0 [Asym.94], trying as far as possible to be coherent and intuitive. Within the hypermedia films, animations, and 3D scenes can be shown, which are particularly stimulating for children.

There are two levels of use. 1) Pupil - for carrying out the varies activities scheduled in the project. 2) Teacher - for (i) checking pupil's work, (ii) making personal notes on such work, and (iii) authoring, thus enabling teachers to choose the animals, to go onto the pupils' worksheets, and to create new worksheets on animals not scheduled in the project. Teachers can also use the Internet directly from the application.

3.3.a The Tutorial The *Tutorial* consists of a book (in tbk), which is a user manual that illustrates the project step by step with guidance on how to use the multimedia part. To make the book as clear as possible it is equipped with images, animations, sounds, and most important, hypertextual links. The photos for use in class for the perception of the human skeleton and the photos of the animals in the Museum are not contained in the Tutorial but are stored in .bmp in a subdirectory and can be called up when required. The animations regard above all explanations of some pupil activities, and give a much better idea of how activities should be carried out than would have been possible with written text. The sounds are used for special effects during the animations and as background music. They can be called up at any moment via a dialog window. The music is basically clips created with the Toolbook and stored in a subdirectory for use as required.

Teachers can click on a hotword to get hypertextual links, and audio-visual support by clicking on parts of the text or images contained therein. At any moment teachers can visualize a map which shows them what they have already read (even if not in sequential order), where they are up to in the general map, and where they can re-enter.

3.3.b Mammals The application was designed and developed so that at a later date other institutions involved in Environmental Education in this geographical area could also interact (Parco di Migliarino-S.Rossore-Massaciuccoli, WWF, LIPU project, holiday farmhouses, etc, and via the Laboratory of environmental education, with "Andrea" data [Andrea.95] and with the whole "world" of the Labnet Project, which for some years has been fully active throughout Italy). Both the functionalities that exploit EnviNet and those services that use ITF were implemented into the application and can be used via dedicated user friendly interfaces.

- **Student level** Bearing in mind the activities, the operating phases, and the worksheets outlined in Section 2b, we will now describe how the pupil activities were developed. Each piece of classwork is recorded in the database so that it can be looked at again at a later date.

1st animal list. The list is compiled via a field equipped with a scroll bar where the list can be written.

Maze game. In this game children find themselves in front of a maze in which there are animals - mammals and non mammals. The aim of the game is to follow a path along which there are only mammals. This is not that simple since when the child makes a mistake he/she is not warned of this immediately but only at the end. The result of this activity is not stored since it is not considered as an activity that can be retrieved either by the teacher or pupil.

Formation of sets The page on which the activity takes place shows two sets, one for the mammals and one for the non mammals, and a number of animal icons with the name of the animal underneath. Pupils have to drag each icon (known as the source) into the correct set (known as the destination) - this is a drag and drop functionality of the new Multimedia Toolbook. We ensured that the image associated with each animal icon (source object) was identical to the icon itself, so that the cursor doesn't change shape during dragging.

Skeleton colouring. On one side of the page is a complete human skeleton and on the other side a dismantled skeleton. Pupils have to colour (using a colour palette) the skeleton parts using the same colours as in the complete skeleton.

2nd animal list The page shows three adjacent scrollable fields which are synchronized in their scrolling: (i) the first shows the list written by the pupil while carrying out the *1st animal list*; (ii) the second and the third are to fill in with information regarding 'what it eats' and 'where it lives', respectively.

Cognitive worksheets. There are three worksheets for each animal, each with photos (zoom option available). The first and third are easy for the pupil to fill in by writing their observations, the second is purely informative and is in text form. For some animals we have created an extra worksheet which is used as an introduction to the other worksheets. There are only a few 'verbal-written' components, while it is possible to show animations (sometimes in 3D) or a short film or photo in which there are hot points which the pupils can click on to get further information by text or audio comments.

Compose skeleton. The human skeleton is composed by dragging the individual elements to the outline of the human body. If the elements are not located correctly then they are automatically rejected. The pupil gets three chances, after which the positions are recorded. If the pupil gets the right result he or she is free to display the four main positions of the composed skeleton (from in front, behind, and from both sides) or to see a 3D animation which shows the rotation of a human skeleton.

Test worksheets. There are five of these: (i) the first is filled in like the one for the formation of sets, but this time it is the names of animals that are dragged into the right sets, they only become icons during dragging (ii) in the second the pupil clicks on dedicated buttons to choose the characteristics indicated, and on the other side, writes observations on the dedicated lines. (iii) the third presents pictures of two skeletons, the pupil has to identify the mammal and give relevant explanations. (iv) in the fourth the pupil collocates some mammals according to their habitat in some Carrol diagrams. This is carried out in exactly the same way as in the first worksheet. (v) In the fifth there are three scrollable fields: in the first pupils can select one from a list of names of animals corresponding to those chosen and/or added by the teacher during authoring (see below). In the second changes in the structure of the animal are written and in the third the related reasons.

- **Teacher-only activities** Teachers can choose from:

Authoring. Teachers can store and update personal data on their students, plus data identifying the class (head of school, name of school, name of class). The application can be adapted to specific didactic needs - teachers can choose which games their pupils will play, which animals to study etc. Also, they can create new worksheets and alternative paths that may be more wide ranging than the original.

Below are some details on the various options the teacher has available.

- ***Insert classes and pupils.*** The data described above (district and name of school, name of class) can be inserted, along with pointers to four tables that are created to contain data on the activities carried out by pupils in a particular class. A page then appears where the names of the teacher and pupils can be inserted.
- ***Change class and pupils*** Teachers can delete the class, delete the school that the class belongs to, modify data regarding the class. Once the changes have been confirmed they are then transferred to the tables for the class in question.
- ***Choose animals.*** This enables teachers to choose some of the animals or to create new worksheets for other animals, or to import worksheets from other users.

In this section of the application the teacher can also modify the worksheets that he/she added beforehand by correcting the text or replacing some of the images. Teachers can even delete the worksheets on an animal that was added beforehand. In this case the three pages that contain them will be deleted, and the name of the animal in question will be deleted from the list of those available.

- ***Choose game.*** Teachers can choose the games by clicking on the name of the required game, though currently only one of the two games is enabled.
- ***Change password.*** Teachers can change the password for entry into the application (ie the one for pupils) and/or the teacher's one.

See classwork Teachers can see the results of student activities. Four scrollable fields are shown for teachers to inspect - pupil name, class, school and district. The page of the activity chosen is then displayed with all the data on the work carried out by the pupil selected. Teachers can then print the result and take notes on the reports on each student, on a page which shows a dedicated 'notebook'. Teachers can obviously not change any of the pupils' work.

Tests. Teachers can put themselves to the test, using the same paths as their pupils and encountering the same difficulties.

Network At all times teachers can use Internet services directly from the application. Teachers can be connected by choosing any URL or one of those belonging to one of the four environmental education centres (cfr. [Sbrana.95]). They can also use e.mail or send worksheets via FTP to other schools that have these applications. Using an FTP program, teachers can also send images of animals to insert into the worksheets, or data on the teacher's school and classwork to show teachers from other schools.

4 Conclusions

We have shown how a Distributed Open Learning/ Teaching Environment can be offered by a museum to interact with schools. We have taken as our case study the didactic itinerary called "The Mammals" which was designed by the Natural History Museum of the University of Pisa as a support for teaching natural sciences in primary schools. We have highlighted the considerable enjoyment expressed by the teachers and students, along with the high didactic efficiency which is a result of a combination of: (i) conception of the psycho-pedagogical and didactic project of the itinerary, (ii) coordination and integration between the experts from the Museum and the teachers of the School, and thus (iii) the coordination and integration between the activities carried out by the students in class and those done at the Museum.

On the basis of these references we have outlined the criteria and modalities with which tools and suitably integrated communication and hypertextual support can be inserted into the Museum-School interaction. We have also shown the delicate relationship between Museum experts, teachers and pupils, not only trying to avoid changing the spirit of the original project, but also contributing to making: (i) the phases more flexible that are needed for the coordination, cooperation and integration between the Museum and School, and therefore (ii) the following (i.e. preparation for the visits to the Museum, visits to the Museum and classwork for the whole experience) more incisive and stimulating for the pupils; (iii) the data collection and assessment stages more systematic and organised for the teacher, for the Museum, and even for the Amminstrazione Provinciale di Pisa, which promoted the technical support for this experience.

The promising results from this experience have stimulated both the 'export' of this type of approach to other contexts of the same nature [Morreale.96], and the extension of research into wider geographical areas and including a more articulated typology of institutions that might interact with schools.

Abstract: In this paper research on legal case solving and knowledge engineering are combined to construct an explicit and principled method for instructing legal case solving. This method will be incorporated in a teaching system: PROSA. The method for instructing legal case solving is materialized as the translation of the desired task and inference structures into actions presented by the system, performed by the student and monitored by the system to provide coaching when required.

Legal Case Solving

A common method in teaching legal problem solving is to make use of (hypothetical) cases that need to be solved by the student. The main educational goal of using this approach is that students have to learn to apply legal rules to specific situations, that is, they have to learn to handle the abstract legal concepts in a concrete situation, select the applicable abstract legal rules and apply these to the specific problem situation. Research on teaching legal case solving ([Crombag, de Wijkerslooth & van Tuyll van Serooskerken 1972], [Gilltay Veth 1974], [Crombag, de Wijkerslooth & Cohen 1977], [Abas, Broekers-Knol, van Hasselt-Pino & Loenhoud-de Wolf 1985], [Henket & van Hoeven 1990], [Franken 1991], [Wessels 1992], [Tunkel 1992]) agrees on four important issues. Solving legal cases is an important way to learn legal problem solving. Secondly, students experience difficulties in solving legal cases, and law professors have difficulties with teaching legal case solving. Thirdly, the main reason for these difficulties is the lack of an explicit, teachable and learnable method and, such a method should be constructed. These observations resulted in methods for legal case solving to be used in legal education. The various methods proposed are, in essence, very much alike.

schematize the case
translate the concrete terms of the case into (abstract) legal terms
select the relevant legal rule(s)
analyze and interpret the (abstract) legal rule(s)
apply the legal rule(s)
evaluate the result
formulate the solution

To be able to provide instruction we need detailed descriptions of the specific actions in the problem solving process in relation with the knowledge to solve the problem. The literature on legal case solving does not provide us with this necessary detail. Therefor we turn to literature on artificial problem solving. [Breuker & Van de Velde 1994] present a coherent overview of computational problem solving methods described in conceptual terms. We rewrite the legal problem solving process, as proposed in the legal case solving literature mentioned above, in the terminology used in [Breuker & Van de Velde 1994].

Artificial Problem Solving

[Breuker & Van de Velde 1994] describe a collection of problem solving methods developed in Artificial Intelligence and knowledge engineering. They describe the characteristics of knowledge based problem solving. A central feature in this description is the expertise model. The expertise model expresses an understanding and rationalization of some problem solving behavior by describing the knowledge and the way it is used in a particular task. The different knowledge roles are captured in three basic knowledge categories: task knowledge, domain knowledge and inference knowledge. Task knowledge describes (1) a decomposition of the top-level task (task decomposition), (2) what it means to achieve these sub-tasks and (3) when the sub-tasks are to be executed (control). Domain knowledge specifies form, structure and contents of domain specific knowledge that is relevant for an application. Inference knowledge specifies the primitive steps in reasoning in an application and the knowledge roles that refer to classes of domain knowledge statements manipulated by the inferences.

In problem solving we distinguish (1) a problem, (2) the (or a) solution (the product) and (3) the problem solving process. The solution to a legal problem should, in general, contain a justification of the conclusion (for the sake of motivation and control). In legal case solving for educational purposes (1) the solution (product) required by the teacher mirrors the problem solving process, (2) to be able to reach a correct solution the student must be able to follow a structured problem solving process, (3) the problem solving process is expressed in terms of task knowledge, domain knowledge and inference knowledge.

The application PROSA (PROblem Situations in Administrative law)

PROSA offers support in accomplishing the (sub)-tasks. The task and inference structures are translated in actions presented by the system. The student reacts and PROSA monitors this performance. The system is able to interpret the students performance on the basis of the actions and provides coaching when required.

We illustrate the approach with a typical administrative procedural law case as used in a course on administrative law. We limit ourselves to the sub-tasks (1) schematize the case, and (2) translate the terms into the case to legal terms.

An Example of a Problem Situation in Administrative Procedural Law

A legal case is a description of a problem situation in non-legal terms, for which a solution is required from a legal perspective. A case describes a number of subjects, objects and events. The subjects and objects play different roles in the events and there are causal and teleological relations between the events. It is almost inevitable that a description is incomplete. The implicit facts and events are part of the problem situation and can be made explicit to complete the description. A criterion for a *good* legal case constructed for educational purposes is that the implicit facts and events can be inferred (almost) equally by the majority of the students.

In our example the case description is followed by a question. To solve the case is to formulate an answer to this question. In legal problem solving it is a must that the answer contains a conclusion and a description of the problem solving process.

> The municipality X has serious parking problems with trucks causing nuisance. The relatively narrow streets house many drivers, who park their trucks in these streets, especially during week ends and at night. The trucks cause many dangerous situations and are the source of complaints about noise and impediment of view. The residents of the houses in the streets where the trucks are parked have enough of it and decide to take action. They collectively write a letter (dated April 1, 1994) to the Mayor and Aldermen of X. They ask them to take suitable measures. Mayor and Aldermen answer by sending a notice in which they acknowledge receipt, state that the request is dealt with and that the residents will be informed as soon as possible.
>
> After three months the residents still did not receive an answer, they repeat there request in a letter dated July 1, 1994. On July 14, 1994, Mayor and Aldermen write that they will take a series of measures. Some of the streets where the trucks have no business, are provided with a long time parking prohibition for trucks. To be able to do that a parking excess regulation is needed. Such a regulation, however, can only be established by the city council. The letter of the Mayor and Aldermen also comes to the attention of the truck drivers. They are strongly opposed against the proposed measures. The truck drivers decide to take action. The removal firm Jansen also decides to take action. One of the truck drivers leaves it to her employer to take action. On August 15, 1994, the city council draws up a parking excess regulation. This regulation is put into operation on October 1, 1994.
>
> What actions can the truck drivers and by the removal firm Jansen take against the letter of Mayor and Aldermen dated July 14, 1994?

Part of the Task Structure for Solving a Legal Case

The sub-tasks (1) schematize the case and (2) translate the concrete terms of the case to (abstract) legal terms described in the terminology of [Breuker & Van de Velde 1994].

```
task schematize case
   task-definition
      goal: a schematized case
      input: a case description in which facts and events are explicitly and implicitly
      present in the form of an unstructured story
      output: a case description in which facts and events are explicit and structured
   task   body
      sub-tasks: complete case terms, sort case terms
      control-structures: schematize case =
      repeat
      complete case terms
      sort case terms
      until all terms are complete and sorted

task translate  case terms into legalities
   task-definition
      goal: translation of the case term into legal terms
      input: an explicit and structured case description
      output: a set of terms that are classified as legal terms
   task   body
      sub-tasks: select case term, classify case term
      control-structures: translate case terms =
      repeat
      select case term
      classify case term
      until all terms are selected and classified
```

Part of the Domain Knowledge

[Valente 1995] distinguishes types of legal knowledge, each type has its own form, structure and content and plays a specific role in the problem solving process Two important types of knowledge in legal problem solving are knowledge of the world and normative knowledge. A model of the administrative procedural law world describes the agents, objects and actions that are active in that world. For example:

```
administrative  body
: supertype [agent]
: subtype [a-body, b-body, 3-body]
: seat (string)
: status (authorized; unauthorized)
: representative (yes, no)

party concerned
: supertype [agent]
: subtype [person, administrative body, other_entity]
: interest (own; general_and_collective, objectively determinable, existent, personal, direct)
if-and-only-if            (party concerned (administrative body) )

An Example of the Interaction in PROSA

The interaction between PROSA and the student is designed on the basis of task and inference structures. These structures are translated into actions on the screen. PROSA presents the case description to the student. The first task in the task-structure is: schematize case. PROSA requires the student to perform action 1 to 4.

(1) the completion of the case description (turning implicit facts and events into explicit ones)
The system support consists of offering the case description with dotted lines in the text where something is missing in the case description. The required action of the student is to fill in these white spots.

(2) the sorting of subjects, objects and events
The system support consists of offering a table with columns marked agents, objects and actions. The required action of the student is to select a (any) term from the case description and drag it to the table [Fig. 2].

(3) the appointment of roles to the subjects and objects

(4) the description of the causal relations between the events (actions)

The next task in the task structure is: translate case terms in the case into legal terms
PROSA requires the actions 5 and 6.
(5) the selection of terms from the case
The system offers the complete and sorted case description. The action required is to take a term from the sorted terms list.

(6) the classification of terms
The system presents the list of terms ready for classification and the domain knowledge model (in this example the model of the knowledge of the administrative procedural world). The student action required is to match a term from the list with a legal term in the domain model [Fig. 3].

Summary

To be able to organize a principled instruction of systematic legal case solving, we combine research in the field of legal case solving and artificial intelligence. The categories of knowledge involved in the task of legal case solving are described as task knowledge, domain knowledge and inference knowledge. In legal case solving it appears that the solution should reflect the case solving process for the purposes of motivation and control. The inference structure is therefor translated into actions presented by the system. PROSA monitors the student when she is engaged in an action and provides coaching. Future research will focus on the following subjects: (1) different ways to present a legal problem situation, (2) a description of the remaining (sub)tasks, and (3) the formulation of decisions on how to interfere in the student's problem solving process and when to interfere.

Abstract: Much of the rhetoric surrounding the World Wide Web celebrates the advantages of the "virtual" (and by implication, immaterial) world. In contrast, we see the Web as potentially enhancing the practice of handicrafts. This paper reports on recent developments in implementing a "Platonic Solids Applet" in Java to permit students to select and decorate folding nets for polyhedral solids made from paper. We describe both the applet and the original paper-sculpture design application, *HyperGami*, to which it is related; we describe ongoing work toward creating a mathematical children's book integrated with Web-based elements; and we discuss the strengths and limitations of the Web in the practice of handicrafts.

I. Introduction

Much of the current rhetoric surrounding the burgeoning popularity of the World Wide Web emphasizes the Web as an emblem of "virtuality." In this vision, the primary advantage of the Web lies in its ability to allow human beings to transcend the limitations of time, space, the body, and the physical world generally. Those interested in art and science may visit virtual galleries and museums; students may attend virtual classrooms; experiments may be performed in virtual science laboratories; social structures are developed and cultivated within virtual communities and "worlds." In every case, the implicit assumption is that the conditions of physical embodiment—in actual laboratories, classrooms, museums, bodies—collectively represent a barrier or expense to be overcome by a more efficient culture of incorporeality.

Eloquent statements on behalf of this vision of technology are not hard to find. In Nicholas Negroponte's book *Being Digital*, he writes, "In the same ways that hypertext removes the limitations of the printed page, the post-information age will remove the limitations of geography. Digital living will include less and less dependence upon being in a specific place at a specific time...." [Negroponte 1995] A similar theme of unlimited possibility and abundance is invoked by Michael Benedikt in his introduction to *Cyberspace*, a collection of essays on virtual worlds: "Cyberspace: Through its myriad, unblinking video eyes, distant places and faces, real and unreal, actual or long gone, can be summoned to presence.... Around every participant, this: a laboratory, an instrumented bridge; taking no space, a home presiding over a world... and a dog under the table." [Benedikt 1991] Sherry Turkle, in her thoughtful (and often cautionary) book *Life on the Screen*, describes a world in which constructs such as friendship, love, and personality undergo a metamorphosis under the influence of computer-based telecommunications: "In the story of constructing identity in the culture of simulation, experiences on the Internet figure prominently, but these experiences can only be understood as part of a larger cultural context. That context is the story of eroding boundaries between the real and the virtual, the animate and the inanimate, the unitary and the multiple self...." [Turkle 1995]

Compelling as these visions are, we do not believe that they need represent a monolithic view of the purpose and meaning of technology generally—or of the World Wide Web in particular. Our own interests lie in the integration of computational media and handicrafts—that is, in the use of computers (and communications) to enrich and rethink traditional creative activities rather than to render them obsolete. In pursuing this line of thought we have developed an educational application named *HyperGami* [Eisenberg & Nishioka 1997], which may be thought of as a design environment for polyhedral paper models and sculptures. Polyhedral modelling is of course a venerable craft activity in mathematics education [Mühlhausen 1993, Pedersen 1988]; but the goal of HyperGami is to move beyond the traditional boundaries of that activity, and to extend its creative potential by permitting students (as well as

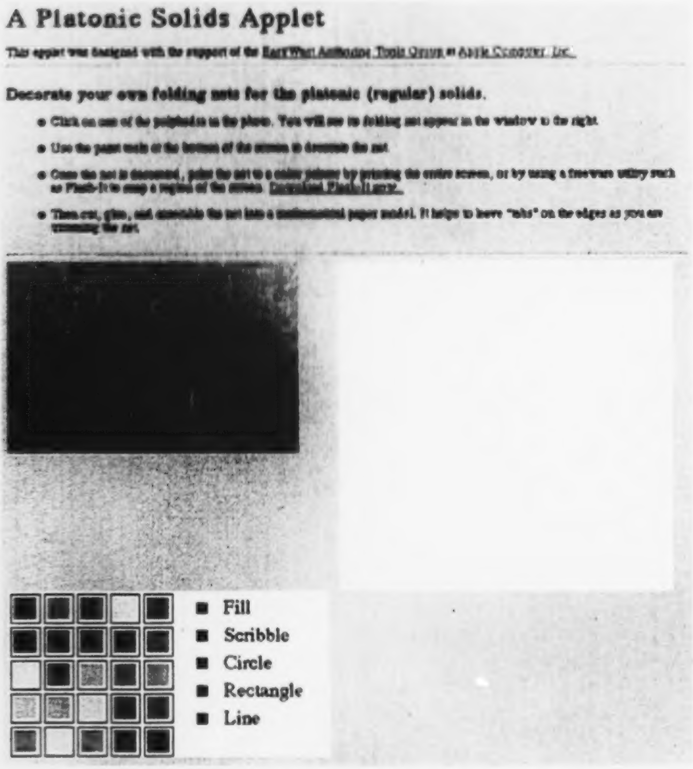
730

professional mathematicians and designers) to create polyhedral models whose levels of complexity and aesthetic appeal would have been unachievable in the absence of computers.

This paper reports on recent developments in making HyperGami constructions and activities available over the World Wide Web. The Platonic Solids Applet is a newly-developed Java program that allows students to create decorated paper models of (HyperGami-designed) polyhedra. Though still in a relatively early stage of development, the Platonic Solids Applet points the way toward more powerful tools for paper sculpture (and for mathematical craftwork) over the Web.

The following section of the paper will describe the current implementation of the Platonic Solids Applet, and its relationship to the larger HyperGami system from which it is derived. The third section will describe a broader project for which our Platonic Solids Applet represents an initial step: namely, the design of a mathematical children's book to be combined with interactive elements and tools available over the Web. The final (fourth) section will describe ongoing work in the HyperGami project with emphasis on the ways in which computational crafts may (or, importantly, may not) ultimately be enhanced by the capabilities of the Web.

II. The Platonic Solids Applet: an Overview



A Platonic Solids Applet

Decorate your own folding nets for the platonic (regular) solids.

Figure 1: A screen view of the Platonic Solids Applet.

The Platonic Solids Applet is a Java applet[1] that permits users to create decorated paper models of the five regular, or Platonic solids (i.e., those solids consisting entirely of regular polygons as faces, and for which

---

[1] The Platonic Solids Applet was written in Java and created using both the Roaster Integrated Development Environment (Natural Intelligence, Inc., Cambridge, MA) and the Sun Java Developer's Kit

BEST COPY AVAILABLE

each vertex is included in the same number of faces). The essential idea of the applet is that the user may select a polyhedral object depicted in a photograph; the program then supplies the user with a "folding net" for that object (a two-dimensional pattern that can be folded into the desired solid). This folding net may be decorated by the user, after which it may be output to a local color printer, cut out, and folded into a tangible solid model. It should, perhaps, be mentioned that while still a relatively simple and early version, the Platonic Solids Applet nonetheless required upwards of 1000 lines of Java code to implement (largely due to the still embryonic state of Java environments and libraries).

The screen appearance of the Platonic Solids Applet is shown in [Fig. 1]. At upper left, a photograph of five solid models is shown; when the user selects one of these (via a mouse-click) the folding net for the chosen solid appears in the larger area toward the right of the screen. [Fig. 2] depicts the result of selecting the icosahedron model (composed of twenty equilateral triangles); here the folding net for the icosahedron is displayed. This net may then be decorated by a variety of means supplied by the paint tools region at bottom left. In [Fig. 2], the user has employed these tools to add a circle, rectangle, line, and "scribble" decoration to the net; she has also filled several of the triangles in the net. The paint tools support these sorts of decorations in the standard manner: for instance, to create a circle, the user chooses a color (from the pre-supplied set in the paint tools box), and then chooses the "circle" radio box. She proceeds to press the mouse button down at the point where the desired circle should be centered, and holds the mouse button down, dragging the mouse cursor to the desired radius of the circle before releasing it. [Fig. 2] depicts a similar (and likewise standard) method for drawing a "scribble" in freehand fashion using the mouse.

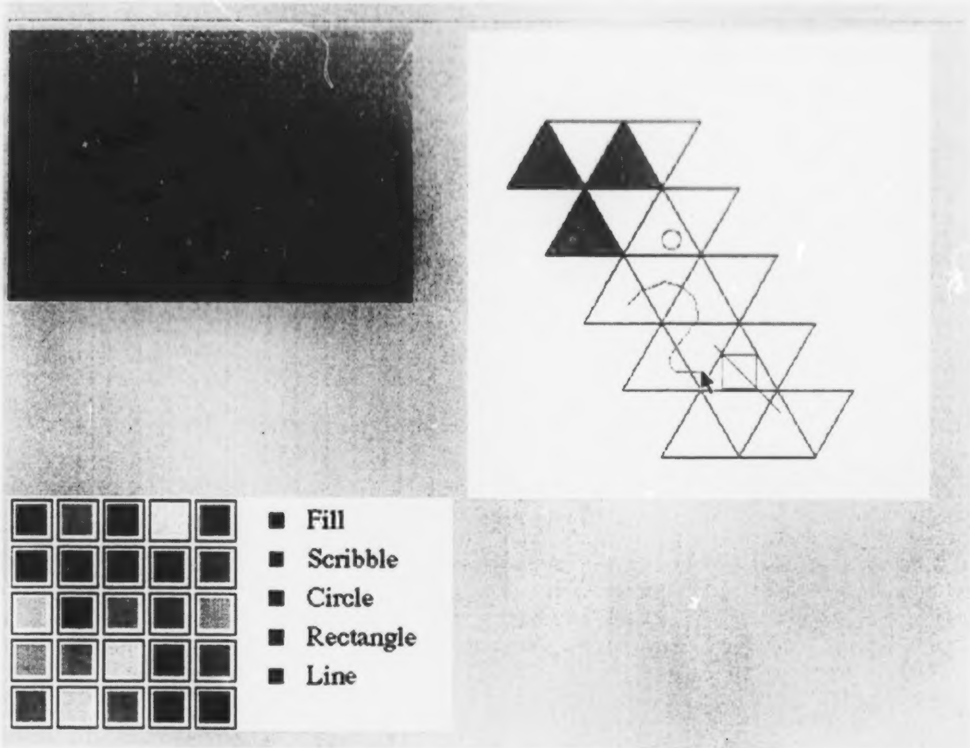


Figure 2: The process of decorating a net for the icosahedron (the shape at upper left in the photograph).

(Sun Microsystems, Inc., Mountain View, CA). The applet may be viewed by following a pointer from the URL:

http://www.cs.colorado.edu/~l3d/systems/hypergami/

Note that the character "l" in "l3d" is a small "L", not a numeral "1".

BEST COPY AVAILABLE

In its implementation, the Platonic Solids Applet represents an initial step in combining our existing HyperGami system with Web-accessible tools and activities. While the user of the applet may, for instance, decorate folding nets, she cannot do so in nearly the range of methods available in HyperGami (which include patterns, textures, programmable gradients, and turtle graphics, among many others). Perhaps more importantly, the central activity in HyperGami is the design of new, never-before-seen custom polyhedra; this is achieved by applying a variety of "customization operations" to starting shapes. [Fig. 3] illustrates the idea: here, we have begun with a HyperGami icosahedron; we have "sliced off" the upper portion of that shape; stretched the remaining portion; and finally, added a "prism cap" at the top of the shape. The HyperGami system is then capable of unfolding this shape to yield the folding net depicted in [Fig. 3].

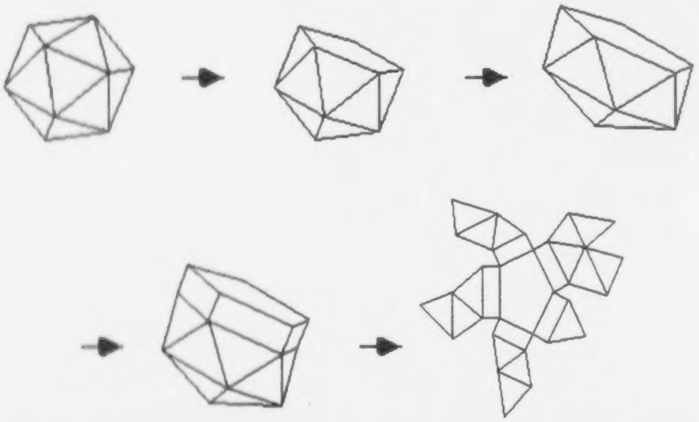

Figure 3: Designing a customized polyhedron in HyperGami. An icosahedron is sliced, stretched, and capped; the "unfolded" pattern is shown in the final stage.

The Platonic Solids Applet is, in its current stage, intended only for the decoration of existing HyperGami solids (our running version includes the five regular solids, but other photographs and solids would of course be feasible additions). The applet cannot be used, however, to design new solids and nets; for this, the full HyperGami system would still be needed.

III. An Interactive Children's Book Blending Mathematics and Art

The Platonic Solids Applet, besides making HyperGami polyhedra available over the Web, is also part of a broader and more ambitious project in mathematics education—one including both traditional and distance learning media. We have recently completed a set of polyhedral constructions for a mathematical children's book entitled "AlphaBetaHedra"—an alphabet book of paper sculpture. In this book, each letter of the alphabet is represented by a photograph of a paper sculpture based on classical polyhedra. Two examples are shown in [Fig. 4]: the letter "F" (for "finger puppethedra") and the letter "G" (for "greenhousehedron"). Elements of these sculptures include the dodecahedron (the head of the pirate finger puppet), the cuboctahedron (on which the body of the soldier finger puppet is based), and the small stellated dodecahedron (the "flower" shapes in the greenhouse).

Our goal in developing "AlphaBetaHedra" is to combine the book with activities (or perhaps partial constructions) that are available over the Web. Readers of the book might be supplied with folding nets for some of the constructions in the book; other constructions could be made available through means such as those suggested by the Platonic Solids Applet. In this fashion, the Web would not be used as a primary means of presenting educational material, but rather as a means of enriching the potential of traditional media. It should also be mentioned that "AlphaBetaHedra" is only the first of what we hope will be a series of books designed in the same spirit—i.e., books that refrain from "preaching" mathematics and instead integrate the subject into a more natural and uncontrived framework in children's literature. We are currently at work on a book that moves beyond "AlphaBetaHedra" to include a narrative, fantasy-like story line.

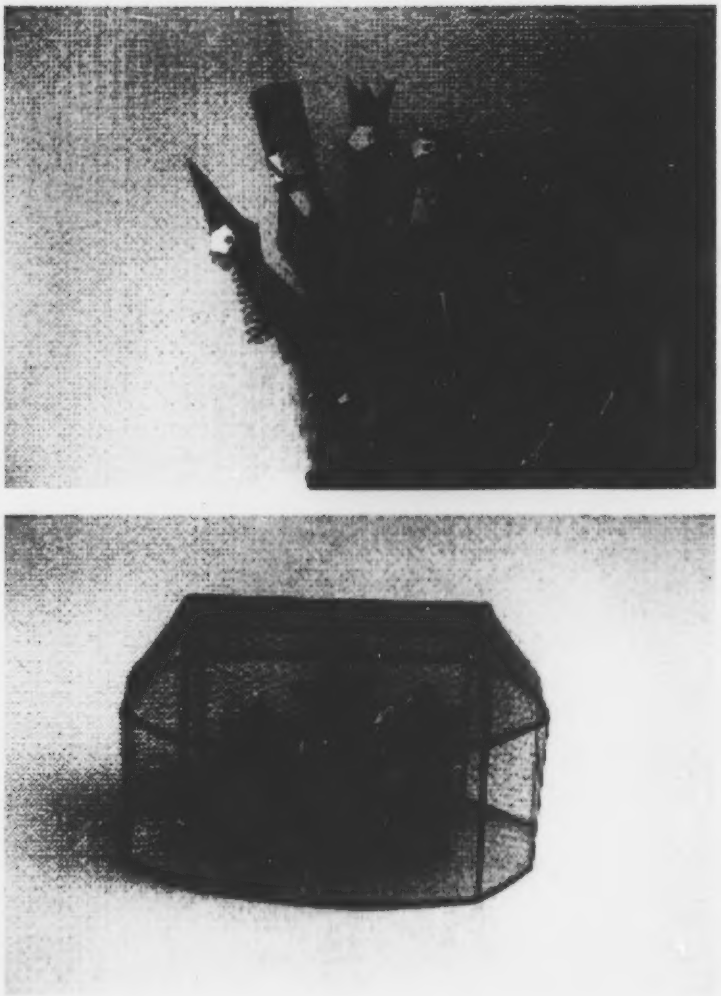

Figure 4: "F for finger puppethedra" and "G for greenhousehedron" from *AlphaBetaHedra*.

IV. Further Directions in Using the Web to Support Computational Crafts

There are certain obvious advantages to using the World Wide Web to support tools like the Platonic Solids Applet—and, more generally, to support the integration of computational media and handicrafts. Extended communities of students (and professional craftspeople) may share insights, experience, and advice; even more interesting, they may share specifications for constructions in various stages of completion. We can envision, for instance, the creation of HyperGami paper sculpture exhibits—real-world exhibits, existing in actual studios—that may be visited both in "real life", and over the Web, and that may be extended by their visitors. (People might, for example, send in folding nets for new constructions which could then be printed out and constructed by member of the exhibit staff "on-site.") In this fashion, a physical space of crafted objects may be enjoyed, studied, and contributed to by a widespread group of enthusiasts.

Despite these optimistic scenarios, however, we feel it important to note that there is an inevitable—perhaps productive—tension between the "virtual" aesthetic of the World Wide Web and the homey, earthbound pleasures of working by hand, with traditional materials. Our own feeling is that systems such as HyperGami and its eventual Web-based cousins—indeed, technological systems generally—should be

BEST COPY AVAILABLE

judged according to how well they enrich the totality of lived experience, both physical and virtual. As Allucquere Rosanne Stone writes, "[I]t is important to remember that virtual community originates in, and must return to, the physical.... Even in the age of the technosocial subject, life is lived through bodies." [Stone 1991] For our part, in a world increasingly defined by the apparent freedom of the disembodied community, we sense a certain longing for the restraints embodied by the behavior of paper, wood, clay, glass, metal, and wax. We hope that innovations such as the World Wide Web may eventually help to intensify the human relationship with materials, and thus to soothe the tensions that they have played such a large part in creating.

Acknowledgments

We are indebted to the ideas and encouragement of Hal Abelson, Michael Mills, and Jim Spohrer, among many others. Thanks to Gerhard Fischer and the members of the Center for Lifelong Learning and Design at the University of Colorado for providing an intellectual home for our efforts. This work has been supported in part by the National Science Foundation and the Advanced Research Projects Agency under Cooperative Agreement CDA-9408607, and by NSF grant REC-961396. The first author is supported by a fellowship from the National Physical Science Consortium; the second author by a Young Investigator award IRI-9258684. Finally, we would like to thank Apple Computer, Inc. for donating the machines with which our research was conducted.

Abstract

Eye Mark Recorder has been introduced to analyze the behavior of a learner seeing subject matter on the CRT. And several preliminary experiments are made to understand the visual cognition-motion process of human being. The rule-based simulator for visual cognition-motion of human being is developed to explain the experimental data consistently.

1.Introduction

Several media on the computer have been used widely in education.The so-called multimedia on the computer gives us a new educational environment. Many subject matters on the multimedia environment are being developed all over the world. We can use various subject matters on the computer in a classroom now.

But , we feel it difficult to evaluate multimedia subject matters compared to the subject matter developed on the traditional computer. There are several aspects concerned with visual cognition of multimedia contents.

It is important to analyze the visual cognition behavior of a learner seeing the multimedia subject matters on the computer to make variation standard for multimedia subject matters. So, we have introduced Eye Mark Recorder to analyze the visual cognition behavior of the learner seeing subject matters.1)

Education has not been regarded as science but merely as empirical skill so far.

We want to change education from skills to science. We want to realize that by researching the visual cognition behavior of a learner.

In this paper, we report the result of basic experiment in which a learner communicating with computer visually. And we try to construct the parallel production system which can explain and simulate the observed visual cognition behavior of human being based on schema theory.

2.The used Eye Mark Recorder

The used Eye Mark Recorder (hereafter we call it EMR.),NAC EMR-600 is shown in Figure 1. The eye mark of the testee is usually analyzed by a human researcher in ex post facto way . The movement of eye mark longer than 1 second can be analyzed in this approach , but the movement of eye mark in the short time range from 10 msec to 100 msec cannot be detected by a human researcher. So , it is necessary to develop a measuring system to detect eye mark data in this short time range.

We have developed the calibration system for EMR which can detect 600 eye mark data per sec to analyze the visual cognition behavior of a human being.(Figure 2)

Using the real time data obtained from the calibration system , the computer can vary what is shown on the CRT quickly. As a result , some environment which can respond quickly with eye movement of human being has been developed.

Figure 1. The used Eye Mark Recorder ,Nac EMR-600

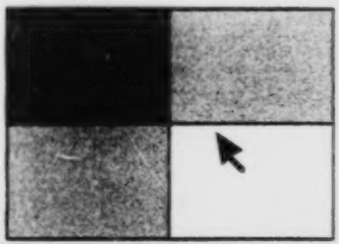
3.Flipper Game

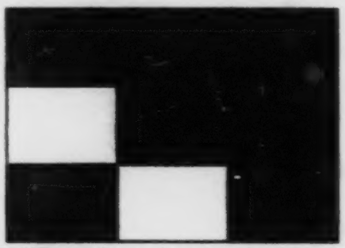
There is a computer game called Flipper(Figure 3).A player of this game moves mouse to select the squares divided on the screen, and then he can vary the color of a selected square by clicking mouse. Six colors are used in this game.

The color of selected square changes in the cyclic sequence. For example ,purple , red ,green , blue and so on. On the other hand , the color of each square varies randomly at regular intervals in time on the CRT .When the colors of all the squares coincident , then the game is cleared. So , a player of this game must vary the color of squares as fast as possible.

The player can confirm which square is selected by seeing a mouse pointer controlled by himself in this original Flipper game.



a) Original Flipper Game the arrow designates mouse pointer



b)The Modified Flipper Game plus(+) designates eye mark pointer

Figure 3. Flipper Game

We modified the original Flipper game into one which selects and changes the color of selected square using eye movement. We have developed four types of modified Flipper games below (Table 1).

		selection	select way	pointer
type1	●	Eye	Mouse buttom	Eye Mark
type2	■	Eye	Mouse buttom	Nothing
type3	○	Eye	Gaze	Eye Mark
type4	□	Eye	Gaze	Nothing
type5	×	Mouse	Mouse buttom	Mouse pointer

Table 1. types of Modified Various Flipper Games

type1
A player can select a square by staring at it . And he confirms his selection by seeing his eye mark pointer on the CRT. And he can change the color of the selected square by clicking the mouse.

type2
In this type of modified Flipper game , the eye mark pointer is not indicated on the CRT. So , the player must change the color of square using mouse without the help of eye mark. We expect high switching efficiency in this case , but the learner doubts if this square is really selected or not ? So, he hesitate to click mouse in some case.

type3
In this modified version of Flipper game , the player need not click the mouse to change the color of the square but he has only to gaze at the square .If the eye mark stays in a square for 0.6 sec , the system automatically changes the color of this square in predefined cyclic order. In this case , the eye mark pointer is generated on the CRT , so the learner can select a square with help of eye mark pointer.

type4
In this type of Flipper game , the eye mark pointer does not appear on the CRT. So the learner must select a square without the help of eye mark pointer. The highest switching efficiency is expected ,but the learner is puzzled which square is selected by his own eyes in this modified type of Flipper game.

summary of modified Flipper games
The observation of the behavior of the learner playing modified Flipper games from type 1 to type 4 is summarized in Figure 4.

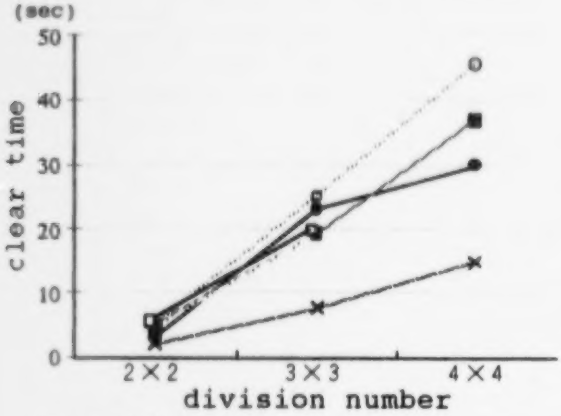


Figure 4.Used time to clear Flipper games

The number of divided squares is plotted in horizontal axis , and the time used to clear a game in each division is plotted respectively in vertical axis.
Type 3(Type 4) is the most difficult for a player.
Type 5 is the easiest. It is the original Flipper game using mouse.
Type 1 is almost the same as type 5 in 5*5(five times five) division in our preliminary observation , but there is statistical fluctuation in our data.

To explain these results in detail , we should construct the model which can explain the cognition-motion process in human brain. This will be discussed in chap.7 in detail.
We are aware that eye movement can be applied to the man-machine interface which requires quick response. But, there is a serious problem. It is not so comfortable for a learner to use his eye movement continuously. Our learner were often tired from using eye movement to select a square in these modified Flipper games.
We need to think of how to avoid this defect in man-machine interface using eye movement.

4. Determination of focus point

When a user fix his eye on the point P on the CRT , detected user's eye mark fluctuates around point P shown in Figure 5. $^{2)}$The neighboring eye marks are grouped into focus region of point P when mutual distance of constituent is smaller than focus size. Focus point of P is defined as the mean of the coordinates of points belonging to focus region.

In the actual case , this focus point of P does not always coincident with point P. The system may use this focus point to guess what is seen by the user.

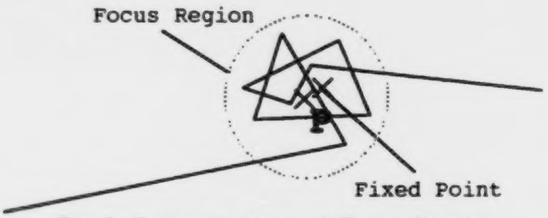

Fig.5. Determination of Focus Region

The user fix his eye on the some regions on the CRT such as pull down menu in Figure 6 to communicate with computer.When focus point is included in this region , the system guesses this region is seen by the user. When a user reads a sentence shown on the CRT , focus points corresponding to each character are obtained.3),4)

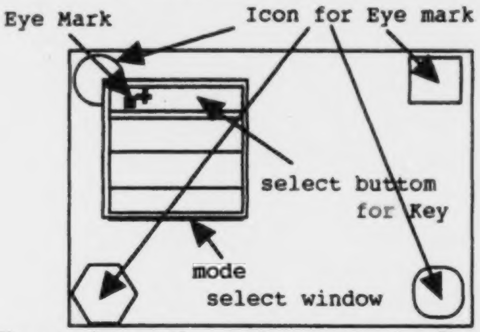

Figure 6. The new interactive environment using Eye Movement

The points corresponding to the movement from a character to another and to blinking are not grouped into focus region.

The number of focus point may vary depending on the value of focus size. The dependence of the number of focus point to focus size is shown in Figure 7.

We decide 1.6 degree as optimum value of focus size from these data.

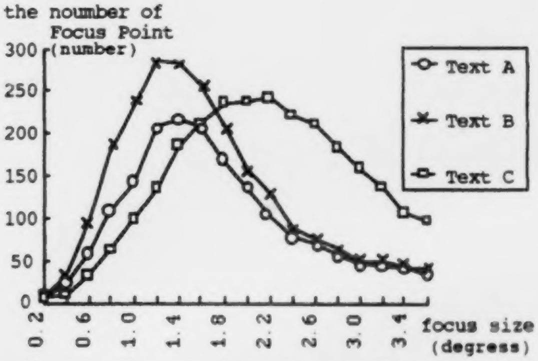

Figure 7. Dependence of the number of Focus Point on focus size

5. Man-Machine interaction using eye movement

The triangle in Figure 8 is an eye mark pointer of the user watching the hypertext on the CRT. This is not the real time eye mark but focus point defined chap.4.

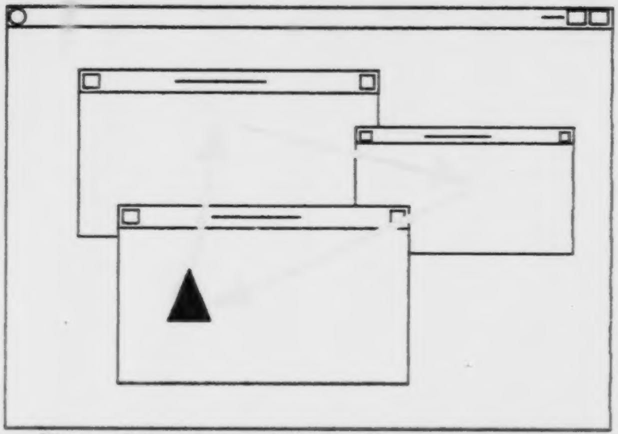

Figure 8.Swiching of Active Window using eyes

When the user moves his eye from the front window to the buck window, the focus point moves from the front window to the back window, then the system automatically changes the back window to the active window. We made our user select an pull down menu on the CRT using eye movement . The menu which has height about 3 degree can be selected safely using eye movement. But this manipulation to select pull down menu using eye motion is not comfortable for some users. But changing of windows using eye movement is comfortable manipulation for all users.

We have developed another mechanism to help a user to select window and menu not using the coordinates of eye mark but using velocity of eye mark.

When a user moves his eyes from a window to another , the velocity of eye mark can be detected by the system. So the system can guess this user want to change the window using the information of velocity of eye mark without detecting the final position of eye mark. The quick manipulation may be expected using velocity of eye mark instead of the coordinate of it.

In Figure 6 , there are four icons on the corner of CRT. If a user wants to select an icon , then he moves his eyes in the direction of the icon from the present point pressing reserved key for this type of selection.

6. The analysis of the process of typing text

A learner types text on the paper using keyboard and he compare characters typed on the CRT with a text on the paper(Figure 9). If a learner is a beginner, his eye moves on the keyboard to see whether his finger is on the exact key or not. If he makes a mistakes in typing character , he must delete wrong character and retype exact character. His eye moves from text on the paper to the typed text on CRT , and conversely from CRT to text on the paper.Typing is very complicated process from this point of view.In this research , we made our learner type random text to avoid chunking of characters.

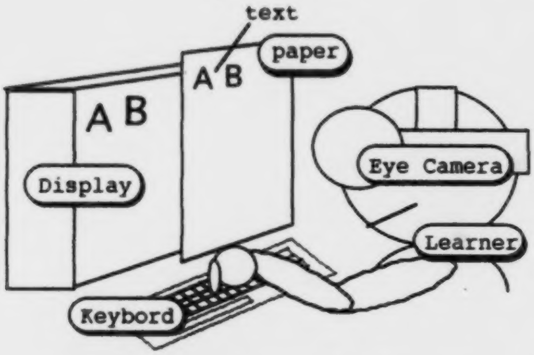

Figure 9.Typing Text using Keybord

To explain and understand this complicated manipulation process, some model for cognition-motion process in his brain is necessary. At first , we used simple serial information processing model for human cognition-motion process to analyze this typing manipulation process(Figure 10).

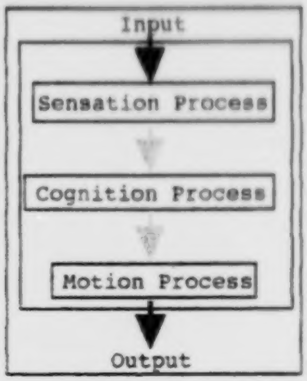

Figure 10 Simple Serial Information Processing Model for cognition-motion Process

At first , we obtain time parameters of individual learner for cognition-motion process using typing data obtained from keyboard scanning. And we try to estimate the time used to type another random characters using the observed parameters.

Of course, several parameters concerned with eye movement cannot be obtained directly, so the capability to estimate the time used for typing is rather small.

The actual used time differs seriously from predicted used time from the Card model using only keyboard scanning data (Table 2).

Testee	Size of Working Memory	Time used for Serch&Memorize	Time used for Typing	Time used for Search&Compare	Rate for Type Miss	Rate for Memorize Miss	Actual Used Time	Predicted Used Time
	Capacity μWM	$R+\mu wmM$ (msec)	T (msec)	$R+\mu wmC$ (msec)	(%)	(%)	(Sec)	(Sec)
A	1	370	410	230	0	0	49.61	92.77
B	2	550	680	710	0	0	76.78	125.15
C	1	140	790	310	0	0	56.03	101.69
D	2	340	410	1090	4	0	67.78	151.19
E	2	650	280	330	0	0	41.28	70.45

Table 2.Cognitive parameters for individual learner

It is necessary to know several parameters concerned with eye movement to improve model. So , we made our learner put Eye Mark Recorder on and type the text.

We can get parameters concerned with eye movement directly in this case, so we can construct more realistic model for typing. As a result , the capability of prediction for used time is remarkably improved.(Figure 11)

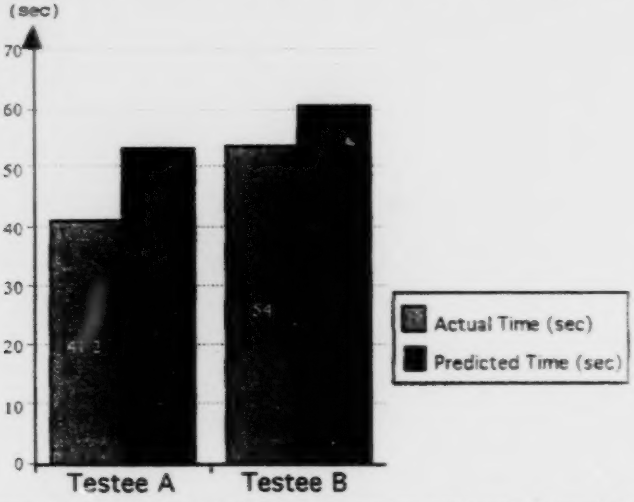

Figure 11. Predicter Used Time compare with actual used time

As is well known , this cognition-motion process may be parallel ,so some parallel model of cognition-motion process is necessary to obtain more realistic model of typing process. This is discussed in detail in chap.7.

7. Recognition-Manipulation Simulator SIMPASI

In the above, we report several results of measuring eye movement of a learner interacting with a computer. These processes are very complicated and depend on the situation in which a learner is confined. As the behavior of eye mark depends on the situation, ordinary data analysis is not so effective.The approach based on reduction is not effective in this domain. The approach to extract the feature directly from the measured data is not effective.

Some models are necessary to extract feature of eye movement from the data.

As is well known , there are several hierarchies of information processing in the human brain concerning visual recognition. The schema theory may be promising as a model of hierarchical visual cognition-motion system.[5)]

So, we have developed rule-based modeling of visual 'recognition . This model is quite general , so it may have capability to explain different cognition processes reported in this paper because many local rule corresponding various experimental situation can be assembled.

We have developed parallel production system called SYMPASI(SYMbolic PArallel SImulator). It is possible to set retardation time for each rule to fire in SIMPASI. So , recognition simulation is generated as a result of successive adaptation of rules. We can tune the system by assembling and modifying various production rules in SIMPASI.

Individual phenomenological facts concerning visual recognition reported in this paper can be assembled in SIMPASI , then overall cognition-motion phenomena is generated by the successive adaptation of rules in working memory of parallel production system. The structure of the rule-based simulator SIMPASI is shown in Figure 12.The part of rules of SIMPASI tuned for modified Flipper game which is reported in chap.4 in detail are shown in appendix .

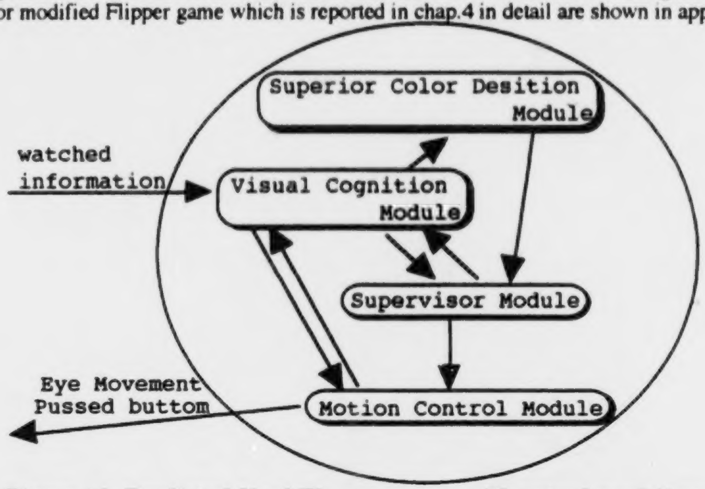

Figure 12. Predicted Used Time compare with actual used time

8. Conclusion

We report several preliminary observations of visual recognition of a learner interacting with a computer. EMR cannot distinguish two points in the angle less than 2 degree. So there is severe restriction of experimental situation.

Vast experimental data is generated in our experiment . The straightforward overall explanation of visual cognition of a learner is difficult if we use ordinary analysis of measured data. So we have developed rule-based simulator of these visual cognition process of a learner. It is very promising to analyze the data using this type of simulator.We have next plan to estimate the level of a learner learning computer language using EMR.[6)]

Implementing Collaborative Learning Through Mainstreaming Faculty Use of Technology

Jane S. Noel, Penn State Lehigh Valley, USA, jsn3@psu.edu
Mary Lynn Brannon, Penn State Worthington Scranton, USA, mlb9@psu.edu

Abstract: The Commonwealth Educational System of the Pennsylvania State University seeks to make learner-centered instruction the norm in all its undergraduate programs. Project Empower has been conceived to quickly bring as many CES faculty as possible into the learner-centered paradigm. Further, the project seeks to equip faculty and campuses with the human and technological resources required to support a contemporary, active and collaborative learning environment.

The Problem:
Evidence shows that students learn more by actively participating in their learning environment. "We learn by doing" is a concept that has been recognized for decades; but why, until only recently, have we submitted our students to the routine of sitting in stationary seats in lecture halls passively taking notes? How do we implement the paradigm shift from passive learning to an active collaborative learning environment? The Penn State University Commonwealth Educational System is working toward a realization of this paradigm shift by empowering its faculty.

Background:
The Penn State Commonwealth Educational System (CES) is a network of 18 campuses across Pennsylvania with an emphasis on teaching and small class size.

The assessment conducted for the 1994 CES Plan for the Future, as well as the individual campus assessments demonstrated a need for a focused unit to support instructional change. The assessment concluded that if the CES is to adequately prepare students for current and future careers, it should offer a curriculum that emphasizes active and collaborative learning. This type of learning activity fosters the group work skills required in today's workplace. In addition, the curriculum should develop lifelong learners,

BEST COPY AVAILABLE 804

since today's college graduates are likely to change both job and career several times during their lives, and need to continually learn new information and skills. Given the globalization of business and communication, students should learn to use electronic communications technologies for research, collaboration, and publication.

Key points that were evident:

- The piecemeal changes brought about solely through the isolated efforts of individual instructors did not create sufficient impetus or support for systemwide change to the type of contemporary learning environment described above.
- A substantial population of "nontraditional" students, more mature and often unable to attend on-campus classes, is both available and eager to access CES programs through distance education technologies.
- The use of communications technologies can enable the CES to make the expertise of its faculty available across the state. CES campuses should be able to offer high-demand programs on a reduced overhead basis via the sound pedagogical use of instructional technologies.

The Center for Learning and Academic Technologies (CLAT), a centrally located unit, was founded in 1995 to support these needs. Three key issues emerged that CLAT would need to address:

Leverage: How can a small, central unit effectively and efficiently produce progress with 850 geographically dispersed faculty and meet the shared needs of 18 campuses across Pennsylvania?

Access: How can CES ensure that faculty, students, and staff have adequate access to the technologies required to develop and to implement a contemporary learning environment both on campus and from remote locations?

Quality and Cost Effectiveness: What quality-control functions can C-LAT both provide and disseminate to ensure that the CES investment in the use of various technologies actually contributes to achieving a learner-centered, active and collaborative college experience for our students? How can we quickly and thoroughly reshape both pedagogical vision and teaching practices? We want to avoid the trap of simply putting old pedagogy out via a new publishing mechanism. Our aim is to radically improve the learning experience of our students.

Rationale:

- The products of instructional innovation must demonstrate and support learner-centered instruction and must be made available to faculty and students throughout the CES.
- Effective learner-centered instruction that can be distributed throughout a statewide system requires excellence in both instructional design and multimedia delivery.
- Faculty must feel ownership of the innovations, and should come to see themselves, both individually and as a group, as effective innovators.
- To be viable, any plan to effect significant, lasting change in a large distributed system must be cost-effective from its inception. This requires powerful leveraging of limited resources. It also increases the likelihood that a program successful at Penn State can succeed elsewhere as well.

Project Empower:

Project Empower, was designed to meet these needs. Faculty were "empowered" with the computer, telecommunications technology, and instructional design support that would encourage a shift from teaching by traditional and passive lectures to an active and more collaborative process that incorporated both lecture and discussion hand in hand in the learning process. Faculty with a desire to switch from an emphasis on teaching to an emphasis on learning could apply for funding for equipment, release time and expert support that would make this shift possible.

Faculty were encouraged to submit proposals. In a simple 2-3 page proposal, faculty had to address a specific instructional problem and suggest how they could use a collaborative solution to solve the problem using a non-traditional approach. Faculty were encouraged to start small with a project that would encompass a few class periods and no more than twenty percent of the class. The project should make a demonstrable contribution to creating a student-centered curriculum.

Learning characterized by project-oriented active student participation and collaboration requires a paradigm shift. The faculty had to be willing to change their classroom role from that of primary "information giver" to that of "facilitator". This in turn, would change the role of the student from passive "listener/note-taker" to "active-learner".

The faculty were provided a one-course release during the Spring 1996 semester, their choice of a Mac or IBM notebook computer, and design support provided by a local Instructional Development Specialist. Each campus was also supplied with a media development workstation and appropriate software.

The response from the faculty was overwhelming with 108 faculty funded for Empower I. Many of these projects were collaborative efforts between faculty using a cross-disciplinary approach or across two or more campus locations. Project Empower has created an arena where both non-computer users and high-end developers can blossom and flourish. Faculty from all disciplines have created new learning environments for their students.

Faculty became the learners also. The various needs of the projects required that new skills be learned - e-mail, conferencing, collaborative learning, group dynamics, presentation, authoring, instructional design, and Web design. Assessment of learning outcomes was an important consideration as well. Faculty put the finishing touches on the project in the Summer 1996 and were required to implement the project in the course for the following Fall semester.

Faculty also report significant changes in instructional strategies as a result of participation in these programs. A survey conducted at the end of the Fall semester 1996 of Empower faculty found:

Teaching Methods	**Pre-Empower**	**During Empower**	**Post-Empower**	**% Pre-Post Change**
Extended lecture	42	31	34	-19%
Small group discussion	24	32	35	46%
Collaborative group work	26	42	42	62%
Asynchronous learning	8	25	24	200%
Computer lab activities	28	42	43	54%
Electronic conferencing	5	3	18	260%
Thematic linkages across disciplines	8	12	13	63%
Team teaching with other faculty	10	9	18	80%
Coach individuals or teams	7	14	20	86%

Table 1: Empower Changes In Teaching Methods

None of the respondents indicated they would go back to teaching as they had before Empower. Ninety-four percent said they intend to develop additional new learning activities for their students. Seventy-five percent indicated a desire to learn more new teaching techniques. Large numbers also indicated they would revise their units and try them again, and seek more opportunities to collaborate with their peers.

Thus the paradigm shift is taking place. Faculty, after completing the Fall projects, immediately began to plan learner-centered activities for Spring semester courses. For example, students in a Physiology course are working in groups to prepare questions from each chapter before the next weeks class meeting. The group leader must submit the questions to the instructor via e-mail the night before the class meeting. The instructor will develop the class discussion based on the questions. The students are responsible for the

BEST COPY AVAILABLE

remainder of the material outside of class. Students are also required to use ADAM interactive CD-ROM's to supplement chapter material. The quizzes for the course will be from material primarily on the CDs.

Faculty have also had to redesign their teaching styles. In another course offered in Computer Science this spring semester a faculty member has implemented problem-based learning. Students are working in teams to reach a programming solution to a real life problem presented by the instructor. Both of these examples represent ongoing changes which were not part of the original Project Empower implementation. These anecdotal examples are perhaps the best representation of the momentum of Project Empower.

One of the key components for a campus to participate in Project Empower was the need to hire and support an Instructional Designer. Consultations with faculty centered around collaborative teaching skills, software skills, learning styles, assessment and evaluation. The concerns of the faculty focused on moving from a lecturer to facilitator, determining the needs of the student audience, communicating to the students what was expected of them, and being able to trust that the students could learn material in an arena other than lecture.

These concerns had to be addressed one by one. The faculty must see the value in audience assessment and learning the teaching skills required in a collaborative learning environment. Pre-tests on group dynamics and computer skills were given to the students. Problem solving exercises were necessary for the students to become comfortable with the projects. It is very important for the students to understand what is expected of them. The faculty must be clear and concise with their material and instructions.

Practically speaking students were required to have e-mail accounts, to become skilled in giving effective presentations, and basic computer use. The faculty had to be cognizant of these needs and had to allocate class and office hour time to the students for learning these tools. The computer labs had to provide the hard ware and software needed to support the projects, as well.

Examples of Empower I projects:

- The Dante Project - MIS faculty and Comp Lit faculty collaborate on a cross disciplinary project where students from MIS are the designers and students from Comp Lit are the content group. Working together these groups produce a multimedia program of Dante's interpretation of sin as it refers to modern day examples.
- Independent Research Project (IRP) - Students are working in pairs on a Genetics research project and pooling data across teams. The final product of the lab will be a scientific paper which each student will produce individually. All instructions about the project and research are delivered through the Web. Shockwave modules and testing on Mendelian and Non-Mendelian genetics are included.
- Engineering problems - Three Engineering Mechanics faculty from three different campuses collaborate on the design of specific real-world problems that will support the content in each chapter of the text. This will be an interactive multimedia program that will utilize calculations and simulations. Students working with the software individually and in groups will obtain immediate feedback on their work.
- English Research - Students use First Class conferencing software to collaborate on development of a diversity related bibliography of Internet research sites.

Student Performance Indicator	**Percentage of Faculty Reporting**
Learned unit content better than before	62%
More interested in content than before	67%
Motivated by group work	54%
Spent more time on unit than before	46%
Picked up technology skills quickly	62%

Table 2: Indicators of Improved Student Learning in Empower Units

807

Instructors' reports of student performance were similarly encouraging. The data in Table Two suggest that increased motivation and time on task were achieved and, as predicted in the literature, did indeed contribute to improved learning.

In addition, faculty reported that students gained additional skills that, at Penn State, we consider essential outcomes of a college education. These included:

- Critical thinking
- Problem solving
- Oral communications
- Group processes, teamwork

As displayed in Table Three, the increased use of the computer lab for asynchronous work, including collaborative group projects highlights the limitations of lab-based student computing.

Said lab congestion limits amount of computer-based work assigned	39 or 75%
Said labs lack the quality of computer resources needed to create more Empower units	45 or 87%

Table 3: Computer Lab Limitations

Among the technical limitations most often cited were the need for updated computers, better Internet access, and longer lab hours. In a related project, faculty reported that average students learned Internet skills twice as fast as honors students in a different section of the same course. The most likely difference was that these students had their own laptop computers, while the honors students not involved with the project could only learn when they could get a seat in the lab.

Our plan, therefore, is to increase the number of students bringing up-to-date laptops to campus, and thus at least limit the growth of demand for lab time and equipment. We are rapidly approaching the end of computer lab-building at the Commonwealth campuses. With machines constantly needing replacement, the labs are not economically viable. And no matter how many lab seats we add, we are unable to even keep up with increasing demand.

Beyond Project Empower

Project Empower is the first step in the three level pyramidal arrangement of projects that describes our system for generating and supporting instructional improvement and related technology use. As shown in the last illustration, each level uses a particular set of tactics and system support to achieve its outcomes.

At the next level up, Project Vision now builds on empowered courses with faculty interested in engaging in full-course development and delivery. At this level students are also "empowered" with the needed technology.

Vision work results in courses that are almost ready for export around the system, via Core projects. Core projects engage C-LAT staff directly with faculty in creation of integrated multimedia-live-and print course packages that can be used by faculty throughout the system. These courses enable us to reach more distant or location-bound students. Students from around the Commonwealth are able to interact electronically with the instructor and other students.

STRATEGIC PLAN

Abstract

The Baltimore Learning Community, funded as a U.S. Department of Education Technology Challenge Grant, is creating a learning community through use of high quality digital science and social studies resources and high-speed networking. The project is a consortium of public and private organizations including The University of Maryland, The Baltimore City Public Schools, Discovery Communications Inc., Apple Computers, U. S. The National Archives, and the Space Telescope Institute. When implemented, science and social studies teachers will have access to images, text, WWW sites, and full motion video via high speed connections to the Internet. The project employs a client-server configuration with client machines installed in middle school classrooms and downloadable digital resources available from a server. Video streaming also will be supported, with all resources available "on demand" from the server or the World Wide Web. A customized dynamic query interface supports teacher access to the resources.

Technology and Modern Views of Learning

Recent research conducted in a variety of domains, has lead to a rethinking of teaching and learning in content classes. As the characteristics of the 21st century work place, with its reliance on telecommunications and information technologies have become more well defined, it has become clear that students must demonstrate competency in core subject area courses that involve complex thinking and problem solving has. For example, curriculum reform initiatives are under way in Great Britain [Barnett, 1992], Australia [Nicholoson, 1993], Spain [Tarrago, Santallusia, & Marti, 1993], and The Netherlands [van Weer, 1992] where informatics is viewed as a core subject area. Learning in content area classes increasingly is being viewed as process of enculturation, where students enter into "cognitive apprenticeships" with teachers who model the thinking skills associated with a domain [Brown, Collins, & Durgid, 1989]. In the last decade, most national and international standard-setting organization have issued rigorous new content standards that reflect the expectation that students demonstrate proficiency in complex and critical thinking, problem-solving, manipulation of information, communication, and cooperative work. In turn, these new standards have influenced state and national content standards and curricular frameworks that often are intended to serve as benchmarks against which to measure the performance of schools.

Networked Technologies and School Reform

At the same time as notions of learning have evolved, a theoretical basis for learning through information technology has emerged and it is becoming clear that media and method are integrally related [Kozma, 1991]. Video technologies such as videotape and Level 4 videodisks, have become essential tools for teachers in mediating situated learning. However, even though teacher interest in use of video technology has grown drastically in recent years, the VCR remains the dominant form of video technology available for use in classrooms. Videodisk systems are readily available to only about 12% of teachers and regularly used by as few as 5% [NEA, 1991], with most videodisk systems located in high schools rather than middle or elementary schools [OTA, 1995]. There are growing expectations that adoption of networked digital video technologies in schools provides the practical basis for many video solutions. In all likelihood, networked technologies will usurp other classroom technologies as competition for limited school budget dollars intensifies. The clear expectation is that information technology that facilitates distance learning will have a major impact on the organization of schools and the nature of teaching and learning in classrooms for the foreseeable future. Unfortunately, the precise relationship between information technology and school improvement has yet to be described. Even though vigorous school reform efforts are widespread, policy and practice generally have entailed a much greater investment in revamping curricular guidelines and establishing high performance standards than in improving access to information technology [Means, 1994; OTA, 1995]. The project we will describe in the remainder of this paper employs state-of-the-art networked telecommunications technology in a format designed to promote improved instruction in content classes, linked to rigorous performance standards and curriculum guidelines.

The Baltimore Learning Community

The Baltimore Learning Community (BLC) is a collaborative project of the University of Maryland at College Park (UMCP), Johns Hopkins University (JHU), and the Baltimore City Public Schools, funded as one of the U.S. Department of Education Technology Challenge Grant. The goal of this five-year project is to create a learning community through use of high quality digital science and social studies resources and high-speed networking. The project has two major components that both target technology "have not" schools that serve high numbers of students who are academically at risk. One component of the project, lead by a team of researchers from JHU, employs interactive video conferencing and focuses on development of school-community links to facilitate effective school to work transitions. The other component of the project is lead by a team of researchers from the University of Maryland at College Park and focuses on development of effective solutions for integrating high quality digital video and other resources into middle school science and social studies classrooms and linking instruction that uses these resources to rigorous curriculum guidelines measured by a statewide performance assessment. This paper will describe the UMCP component.

In addition to the school and university partners, the BLC also involves a consortium of public organizations and private businesses that have made a major investment in the project. Discovery Communications Inc. participated actively in the development of the original project proposal and is providing digitized video programming from the Discovery Channel and The Learning Channel as well as ongoing technical and conceptual assistance. Apple Computers has donated 40 computers as well as significant technical support. The National Archives and the Space Telescope Institute have provided significant content resources in both digital and non-digital formats.

Overview of System Design

The project employs a multi-format, multi-source approach to providing a wide range of instructional materials in content classrooms. When the project is fully implemented, 12 science and social studies teachers in classrooms in three urban middle schools will have access to still images, various forms of text, WWW sites, and full motion video via high speed connections to the Internet. Some of these resources will reside on a video server consisting of a Sun Sparc 20 workstation running Starlight video server software while other resources will reside throughout the World Wide Web. The project is employing a client-server configuration with client machines installed in the middle school classrooms and digital resources available on a download basis from the server. Upon final implementation, video streaming will be supported, with all resources available "on demand" from the server or the World Wide Web.

Each of the 12 classrooms is equipped with three or four Apple Macintosh 5200 computers capable of displaying MPEG video. These machines are available for student use. In addition, the classrooms also include "planning and presentation" platform consisting of an MPEG-capable Apple Macintosh 5400 computer equipped with a 4gb hard drive as well as one or two large screen "s-video" monitors for classwide display. Presently, each of the schools in the project operates an ethernet-based LAN with a hubbed dial-up connection to a proprietary Internet provider. All teachers on the project also have been provided with Internet access at home. The project will migrate to fiber or a hybrid wired/wireless solution in the last two project years. Currently, the Sparc 20 server resides at the University of Maryland but upon full implementation of the project, the server will be located in the school district and schools will have ISDN or better bandwidth connectivity.

The networking and video-server configurations employed on the project for the most-part use "off the shelf" technologies. This is consistent with the goal of ensuring maximum scalability of all aspects demonstrated on the project. However, the project has required development of two software innovations. These are an indexing system that employs a graphic display for retrieval and previewing of digital resources, and a user interface that links access and use of digital content resources directly to an instructional decision-making and planning process based on curriculum standards. The customized search and explore interface uses a dynamic query interface [Allany & Shnierderman, 1995] to support teacher access to the resources.

Multimedia Indexing and Retrieval System

The multimedia indexing and retrieval system employs a starfield display that allows the user to search for digital resources stored on the local server by subject area, topic, or subtopic. The display crosses topics by standards on two axes and displays variable length bars corresponding to video, graphics, WWW sites, and text resources, and modules previously created by other teachers. The number of each type of resources available on the server varies according to the particular subject area, topic, or subtopic selected and the size of the bar displayed in the starfield corresponds to the number of resources of each type that are available for retrieval. This display is illustrated in Figure 1. Currently, over 1000 objects are stored on the server, and we anticipate that this number will grow to over 50,000 by the end of the five project years.

By clicking on any of the bars in the starfield display, the user can obtain more detailed information about the resources available and then select specific items to preview. The preview mode presents thumbnail images of the resources available on the server so the user can decide whether or not they want to acquire the image for use in the classroom. The preview mode is illustrated in Figure 2. Once the user has decided to use an item, it can be downloaded and stored at the planning and presentation workstation in the teacher's classroom.

Instructional Planning Interface

The overriding goal of the project is to create technological support for instruction in middle school content classes that enables students to meet rigorous performance outcomes. The digital materials that can be accessed in the project are expected to function as instructional anchors that will help teachers create a context within which to situate instruction. Unlike videodisk-based programs in which instructional planning and organization are conducted by the program authors, this project leaves virtually all of the decision-making about how the digital resources will be used up to the teacher. Generally the video content stored on the server is less than 3 minutes in length and is intended to be used within an instructional

context mediated by the teacher rather than to function as a complete instructional program. To assist teachers in this process, a user interface has been created that requires a series of instructional planning decisions before the digital resources stored on the server are incorporated into instruction in the classroom. The interface is an HTML-based form with cgi scripts that support development of Instructional modules that can be stored on the server and displayed at the planning and presentation workstation in each classroom.

Instructional modules can then be used in any context the teacher wishes, ranging from a single, self-contained lesson to a series of lessons that occur over numerous class days. These modules are stored on the server and always available for use in the classroom. The user interface offers a Planning Mode and a Presentation Mode to support module development. To create a module during Planning Mode, the user must specify specific information such as grade level, content area, and curriculum goals the instruction is intended to address. The Planning Mode interface is shown in Figure 3.

Linkage with performance assessment tasks also will be included in the final version of the system, although this function is not included in the current version. The user also is asked to identify activities and tasks that will occur before-, during-, and after-instruction. Once this information has been specified, the path name or URL of resources the user has selected from the starfield display are listed and available for display in the classroom. When the teacher is ready to use the module in class, the resources can be accessed from the list and displayed via the TV monitors. The Presentation Mode permits resources to be displayed in full motion, at full screen under teacher control.

Abstract: Successful teachers have always been able to create an environment in tune with the learning styles of their students. Today's students span all ages and have varied learning styles and backgrounds. Many work under serious time constraints, want to control their learning process, and care that the classroom experience connects to the real world. Today's teachers can make use of scientific educational research which underpins modern pedagogy and electronic communication which expands the classroom into a collaborative, interactive learning environment.

We have significantly improved student morale and performance through a strategy combining collaborative learning with use of the world wide web. Students submit web-based active learner assignments. A subset of these assignments, due just before class, provides immediate feedback concerning the state of the classes' progress. Instructors adjust the subsequent lesson to address the specific student needs revealed by this electronic communication. We have designated this technique Just-in-Time instruction.

Introduction

IUPUI and the USAFA faculty face very similar challenges. The students at both institutions expect course material to be relevant to their career objectives. They work under severe time constraints, and come with a wide range of backgrounds, interests, and academic preparation. To meet these challenges, we turn to the fruits of developments in communication technology of the electronic information age and physics education research.

The digital electronic information age opened with the advent of the microprocessor-based personal computer in the late 1970's. The next phase came with the introduction of multimedia objects such as digital images, digital video and sound. The third phase, the World Wide Web, has become the vehicle for rapid dissemination of multimedia learning resources. The web technology also provides for instantaneous interactivity, essentially eliminating the traditional space and time barriers. Web sites can serve as communication hubs for student-teacher, student-student and teacher-teacher interactions. By providing web-based instructional material teachers can structure the out-of-the-classroom time so the students can use it more productively. Web sites can provide a virtual setting for collaborative peer instruction which has proven so effective in the classroom.

Education research [Redish 1994, Peters 1982, Cope and Hannah 1975] has identified a number of challenges that impede effective teaching and learning. For our students, the most significant of these are: time management, motivation to learn physics, physics vs. the real world, study habits, and academic background.

In addition, a successful career in a technical workplace necessitates the development of critical thinking, good estimation skills, the ability to deal with ill-defined problems, cooperative work habits and communication skills.

The Challenge

Indiana University-Purdue University at Indianapolis (IUPUI) is a public university in an urban setting. It is a major campus in the statewide system of Indiana University with an enrollment of over 27,000 students. Just under 20,000 of these are undergraduates, while the rest attend professional and graduate schools. 12,722 students are full time, 58% are female, and 11.8% belong to ethnic minorities. 79% of the students are employed, most of them (88%) off campus. The average age of the IUPUI student is 26.8 years.

The United States Air Force Academy (USAFA) is a residential four-year military college in a rural setting. The total enrollment is 4,000; about 1,200 fourth class (freshman) students enter each year. The composition of the student body mirrors that of the Air Force officer corps: about 12 percent women and 16 percent minorities. Students come from all fifty states and several other countries. Their common bond is the desire to be military officers.

Physics educational research over the past two decades suggests promising strategies to help students benefit more from their classroom experiences [Redish 1994, Peters 1982, Cope and Hannah 1975]. Students in physics classes must be given control over their own learning processes, must be motivated to want to learn physics, and must be shown the connection between physics in the classroom and the real world. At the same time, they have to acquire critical thinking skills, estimation skills, and problem solving skills, and they have to master a great deal of physics content.

In introductory physics at IUPUI, we deal with all of these challenges. In addition, there are difficulties posed by a student body that is primarily composed of students who are commuters, who have poor academic backgrounds, and who are returning to or first entering higher education after several years in the workforce. Most of our students are on split schedules: in school in the morning, at work in the afternoon, and perhaps back in school in the evening. Although our students are older and more mature than those found at many colleges and universities, they often have poor study habits, and many have mathematical skills that have grown "rusty" since their last educational experience. For these and other reasons, most of our students have little self confidence. Retention is a major problem as a result of these pressures. Commuting students, who are often part-time students as well, have a particularly hard time staying the course. They frequently give up early in the semester only to come back and try again the following semester. Even intelligent, motivated students often must repeat one or both semesters to earn passing grades. Other, less motivated students may question their ability and give up on their educational goals altogether. These problems are not unique to IUPUI or to science and engineering: high attrition rates are common among students returning to higher education nationwide [Cope and Hannah 1975].

At the USAFA, we find that some of our students aren't spending as much time on physics outside of class as the faculty think they should be spending. In other cases, we find that our students are spending a good bit of time, but that the time they are spending isn't very effective or efficient. In many cases, the cause of the problem can be traced to severe student time constraints and limited feedback and support mechanisms outside the classroom. Although the reasons for the USAFA student time constraints -- namely an ever present combination of academic, military, and athletic duties -- are different from those of civilian institution students like those at IUPUI -- namely jobs, families, extracurriculars -- the effects are the same. Furthermore, although our faculty are very available during the day, time-constrained cadet schedules force much of their study into evening hours when faculty are generally not available.

Every one of the 4000 Academy cadets must take and successfully complete two semesters of calculus-based physics. Although each of the cadets excels in one or more academic disciplines, not every student necessarily excels in or is inherently interested in physics; so they often wonder, "Why do I have to take this?" and "How is this relevant to me and/or my Air Force Officer career?" Our efforts try to address and answer these questions. In doing so, we hope to personalize our physics courses by using the same technology that is sometimes criticized as being impersonal.

Meeting the Challenge

The last ten years have seen a number of innovations in introductory physics instruction. Physics courses that produce desirable results all have broken with tradition in one way or another. While our experimental, innovative courses retain the traditional format, they have broken with tradition in several ways. Both the structure of the courses and the instructional strategies have been changed.

Our efforts are founded on a two pronged approach combining technological methods (the web component) with intense personal contact (primarily a collaborative learning environment in place of the traditional recitation section and timely monitoring of student status via the web assignments.) We have added an active learner, around the clock, component delivered on the world wide web, and we have adopted our own version of collaborative learning.

The structural redesign represents a shift to the active learner paradigm grafted onto the traditional lecture/lab/recitation format. The new instructional strategies focus on the problems we have identified in our student populations.

We want to be able to move toward and accomplish individualized learning. We want to be able to start where each student is and help them advance from that point by providing appropriate levels of support and feedback, thus producing enabled students.

We also want to be able to move toward and accomplish interactive learning. We want collaborative student/teacher sessions, and class meetings that engage the students rather than allowing them to remain passive.

Furthermore, we want to be able to move toward and accomplish real-world, relevant learning. We want our students to know how the physics content they learn in physics class is relevant to their careers as science literate citizens/Air Force Officers.

It is important to understand that our use of the web is not intended to reduce the demands on instructors' time, nor is it intended to increase the number of students that can be handled. If anything, the role of the instructor and the involved commitment to individual student needs become even more important.

The web component of the course is intended to address several of the challenges discussed above. It gives students more control over their learning process, provides information connecting the course material to real world phenomena, gives commuting and part-time students an enhanced connection to the learning community, and can be used to provide remedial materials. Furthermore, the web based assignments are carefully constructed and paced so as to provide motivation and aid in study time management. By systematic use of the emerging network technologies, it is possible to break down the space and time barrier and connect to the student outside the classroom at any time.

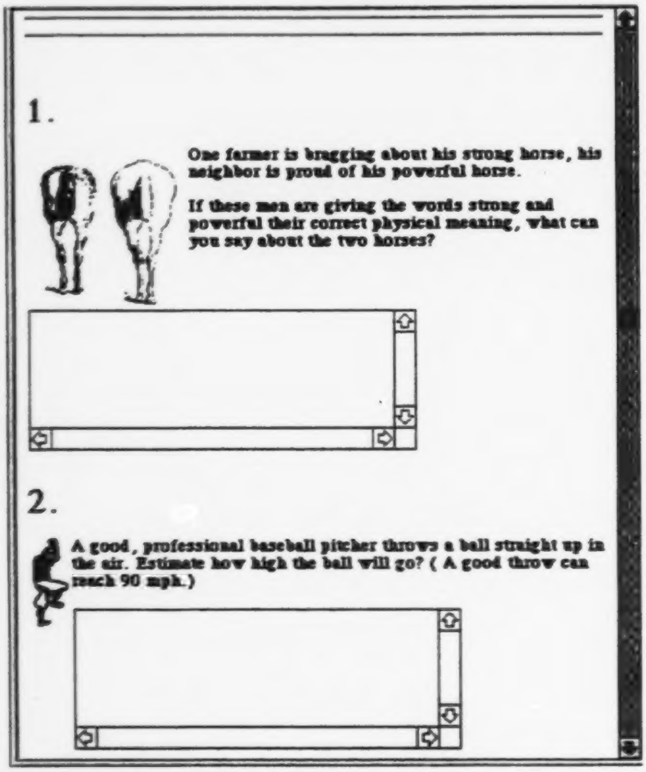
A crucial aspect in the success of our web component has been the offer of "extra credit" through the web material. Three separate pages within the material offer credit: "What is Physics Good For?", Warmup/Preflight exercises, and the Puzzle. We refer to these assignments as "extra credit" for a specific reason. After informally interviewing several students, we concluded that students would not visit the material unless there was a direct academic incentive. We did not wish to reduce the amount of traditional homework; however, students will resent the assignment of extra "required" work if it is imposed with no concomitant increase in the number of credit hours earned. Offering "extra credit" answers both of these concerns, while simultaneously improving student morale.

Each of the web assignments has different educational goals. However, the web assignments also work together in several important respects. By scattering the credit over several different pages, we encourage students to work on physics frequently and in short sessions, a far more effective study habit than a single weekly "cram session." Furthermore, we cash in on the "arcade factor" identified by some education researchers [Malone 1981]. Giving the student multiple chances encourages the student to try again and eventually succeed. This encourages the student to keep up with the course and mitigates the impulse to withdraw because "I am so far behind." Since most of our students respond to these assignments electronically, they are in frequent one-on-one contact with their instructors. Requests for clarification of a particular topic often accompany the their submissions. It may seem paradoxical that the use of electronic technology should enhance personal relationships. However, this phenomenon is not unusual in on-line activities.

The web component also provides crucial feedback to the instructors. One set of web exercises (the "warmup"/ "preflight" exercises, which we discuss in detail below) give the instructors insight into the state of students' knowledge and into the misconceptions that many students bring to the study of physics. This allows instructors to adjust the subsequent lesson to address the specific student needs revealed by this electronic communication. We have dubbed this method Just-in-Time (JiT) instruction, in analogy with JiT production methods now used by many industries. The comparison is not capricious. In both cases, the JiT system improves flexibility, minimizes waste, and provides rapid reaction to unforeseen demands.

These exercises are due a few hours before class. Each includes three questions: the first is conceptual, requiring a response of a few sentences. The second question calls for the student to do a brief calculation including an estimation task. The third is a single-concept multiple choice question.

These exercises are the heart of the Just-in-Time instruction system. Each morning before class the instructor reads the student responses, then has a few hours to adjust the lesson to respond to the students' demonstrated knowledge. Thus far, we have found that the conceptual questions are particularly valuable for JiT instruction. Most instructors (ourselves included) easily forget the misconceptions that many students bring to their first contact with various concepts in physics. As an example, consider the words force, power, and energy.



1.

One farmer is bragging about his strong horse, his neighbor is proud of his powerful horse.

If these men are giving the words strong and powerful their correct physical meaning, what can you say about the two horses?

2.

A good, professional baseball pitcher throws a ball straight up in the air. Estimate how high the ball will go? (A good throw can reach 90 mph.)

Figure 1: Warmup/Preflight exercise from first semester physics

These are generally considered to be synonymous; this document was prepared using a word processor that lists them as such in its thesaurus. However, in physics, these words all have special meanings and the quantities cannot be equated. Students, pressed for time, often miss this fact on a first reading of the book. A warmup/preflight question asking that the students discuss these concepts will motivate many students to reread a few sections. The remainder answer the question based on their preconceptions. These answers (presented in anonymous, edited form) can be used as talking points during the lesson, while the issue is still fresh in the students' minds.

Additional web material provides support and framework, as well as additional relevance and connection to the real world.

The "This Week" page includes course announcements and frequently provides brief notes (with links to outside sources) concerning news items of scientific interest. The button bar on the left edge of the page provides links to several more pages on which the primary content is provided. This page and all that follow from it are completely updated each week.

The "What is Physics Good For?" page serves several of the goals stated above. It is our primary vehicle for connecting classroom theory to real world phenomena. It is also extremely valuable as a motivational tool; it allows us to introduce both the excitement of recent scientific developments and the importance of familiar technological devices into a curriculum that is traditionally limited to the results of the 17th and 18th centuries. The page introduces a subject and establishes a connection to the subject matter being treated in class. These subjects have included, Life on Mars, Electric Vehicles, Superconductivity, Auto Racing, and The World Wide Web itself. After one to two pages written by the instructors, links to outside sources of information are provided. The students are then asked to check these links, use search engines, and respond to a few short questions concerning the week's subject. They submit their results to the instructors via e-mail. This assignment allows the students to explore these topics at their own pace. We have found that students frequently exceed the stated questions, providing unsolicited information often including suggested links for future pages.

As the name implies, the "Puzzle" page presents a physics scenario with an extra twist that requires the student to see beyond the end-of-chapter formulas. This is often accomplished by further challenging commonly held misconceptions. The Hestenes' Force Concept Inventory questions [Halloun and Hestenes 1985] and Eric Mazur's peer instruction questions [Mazur 1996] have a similar character. These questions may appear quite trivial to a physicist, indeed, they may almost always be answered with no need for mathematical calculations. On the other hand, they usually present a significant challenge to the beginning student.

Following the puzzle, the remaining pages offer preparatory materials associated with the weekly lab section, the archive of previous materials, and the "credit check." This last allows students to determine which web assignments they have received credit for, and gain a sense of how they are doing with respect to their classmates.

The last page is the "Hot Stuff" page. This includes materials which are of immediate import. For instance, sample exams are posted here during the week before each test, and the grade distributions are posted after the tests. In addition, breaking scientific news items are posted here if they require more space than a few lines among the announcements.

For the future, we intend to expand and improve our use of the web in several important ways. We will introduce remedial materials in the areas of trigonometry, vector algebra, and basic calculus. This will be particularly valuable to our returning students, many of whom are 5 to 10 years from their last mathematics course. We will expand the laboratory preparation page to include short streaming video clips of the upcoming experiment. This lab prep page already includes an extra credit component related to a data analysis tasks they will face in the lab. We have begun to use student mentors to supplement faculty in the recitation classroom. We have one such student now, and he has made a markedly positive impact. Certain types of advice are simply more acceptable coming from another student, especially as the student is known to have no grading responsibilities.

We have anecdotal evidence that the system is working well. At IUPUI, attendance in the classroom has jumped to 95%. The early withdrawal has virtually disappeared. That means that we are retaining students who, in previous years, dropped the course for psychological reasons and eventually passed. We are still looking at a 10 to 15% attrition rate in the first course and 5% in the second course. This represents students who withdraw at midterm or fail the course. We consider this an acceptable rate. Some of these students start out in the wrong program. About 60% of the students in the first course and 95% in the second course submit material to the web. Virtually all of them visit the web site. At the USAFA, the JiT approach is being tested in a number of sections. Submission response percentages range from 65% to 100%. Anecdotal evidence suggests that student attitudes toward physics are improving. Instructors appreciate the unprecedented JiT access to the wealth of information about their students' progress.

After another semester or so of fine-tuning, we shall proceed to a formal assessment of cognitive gains, if any, which result from Just-in-Time instruction.

Abstract:
It has been proposed that performance support systems can improve the speed and quality of learning by providing the right information when and where it is needed. However, there have been no formal studies comparing a performance support system to traditional training or support methods. This paper describes an initial study which compared a computer-based performance support system with a book for learning and performing a simple task. Results of this initial study are summarized. Guidance on the design of future performance support systems and suggestions for future studies are also provided.

Introduction

Performance support systems are computer information systems which are designed to improve employee performance. Performance support systems aid performance by providing only the necessary information at the right time and supporting training when training is needed [Gery 1991]. Performance support systems allow all employees to have expert-like performance. However, not all jobs are computer-based; many workers are mobile and do not use a computer to do their jobs. In these situations, using a wearable computer to deliver a performance support system can improve the effectiveness of the performance support system. In particular, a wearable computer performance support system can:

- Provide training and support *when* the learner needs it
- Provide training and support *where* the learner needs it
- Provide only the information that is needed at that time
- Allow the learner to control any training that is required
- Provide multimedia (e.g., text, audio, drawings, video) presentation which most effectively communicates the information needed
- Emphasize performance rather than knowledge
- Eliminate time between learning and application of knowledge
- Provide hands-free operation
- Allow the learner to see both the work environment and the presented information simultaneously

The use of a wearable computer with a performance support system is a novel concept in performance support [Ockerman, Najjar, Thompson, Treanor, & Atkinson 1995]. To determine whether a wearable computer performance support system can help people perform tasks, we performed an initial evaluation. In the evaluation we compared the use of a wearable computer performance support system to the use of a book to perform three simple tasks. To evaluate the effectiveness of the wearable computer and performance support system, we developed a wearable computer and a simple performance support system. Each of these technologies is described in the following sections.

Wearable Computer

Figure 1 shows a front and back view of the wearable computer's major components. The user enters and receives information from the computer using a combination microphone/earphone and a head-mounted display. Voice recognition serves as the primary way to control the computer. The computer and batteries are worn on the waist.

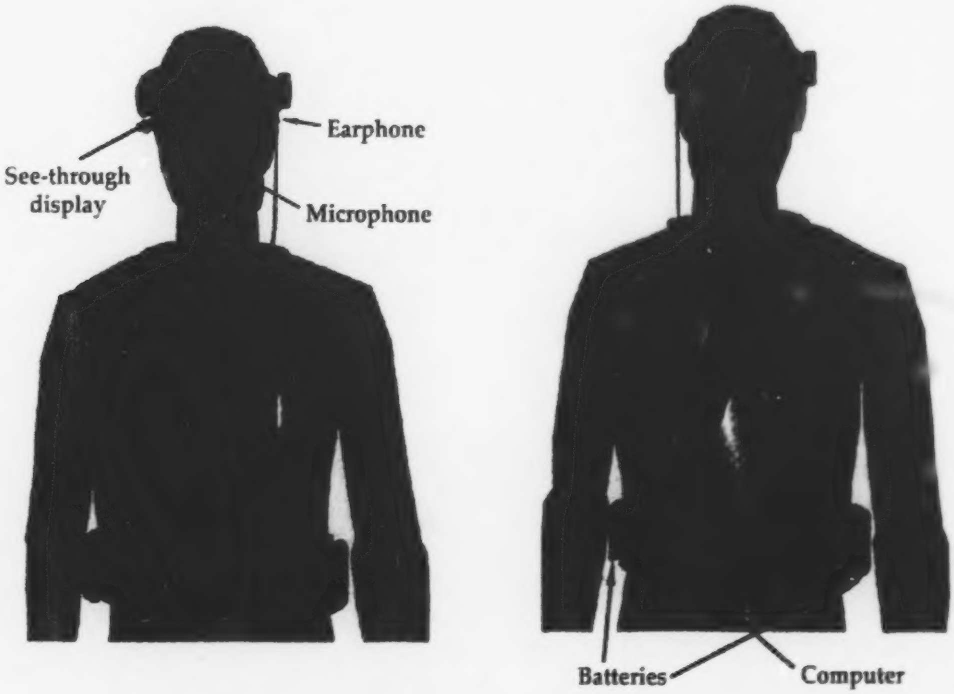

Figure 1: Front and back view of wearable computer components.

Our wearable computer provides many advantages for helping a user to perform tasks. For example, the display allows the user to work while looking at text, drawings, and video. The earphone allows the user to hear explanatory audio narration while looking at information on the display or at the task environment. The microphone, voice recognition software, and our applications allow the user to control the computer via voice so the user's hands are free for other tasks. The computer allows the information designer to use the best medium (e.g., text, graphics, video, sound) to communicate information to the user. The combination of batteries, computer, wireless network, and head-mounted display allow the user to be mobile, getting information when and where the user needs it.

Performance Support System

Performance support systems use specialized software which integrates information, tools, and methodologies to help a user perform a specific task [Gery 1991]. We built a performance support system to teach users how to do origami, the ancient Japanese art of paper-folding [Najjar, Ockerman, Thompson, & Treanor 1996]. Origami is a hands-on, slightly complex task which is unfamiliar to most people. The goal of our system was to allow users to learn to fold a simple jumping frog.

BEST COPY AVAILABLE

To be successful, a performance support system must organize information in a way that is obvious to someone who has not used the performance support system before [Najjar, Ockerman, Thompson & Treanor 1995]. We organized the training information into the following intuitive categories: a brief description of the training goal, the steps to follow to meet the goal, a tool that helps the user correct his or her work, and an on-line library of background information. Figure 2 shows the main menu of our origami performance support system.

Figure 2: Main Menu of Origami Performance Support System

In our origami performance support system, we tried to use media in a way that helped the user to understand and learn the information [Najjar 1995, Najjar 1996]. For example, in the section that has step-by-step instructions, each step is illustrated with a simple static drawing and accompanying auditory instructions [see Figure 3]. To understand the fold described by the step, the user can examine the drawing for as long as desired and have the instructions replayed. However, since paper-folding is a dynamic task, we also provided an option that allows the user to see and hear a video of someone actually folding the paper [see Figure 3]. The wearable computer allows the user to look at the drawings or videos, and listen to the auditory instructions, while folding the paper.

Figure 3: Sample Step from Origami Performance Support System (static drawing and video)

Method

This initial study compared participant performance in three simple tasks while using one of the following two learning systems.

BEST COPY AVAILABLE

- A wearable computer performance support system. The wearable computer shows drawings, audio, and video which demonstrates how to fold a jumping frog. The user also provides basic origami information (e.g., common origami folds and information on origami paper). The user controls the navigation and pace of the instruction with voice commands.
- A book. The book includes textual instructions and black and white drawings to show how to fold many objects and provides basic origami information. The user controls navigation and pace of instruction by flipping pages.

The verbal instructions and static drawings on how to fold a jumping paper frog are identical in both systems. Participants were not given any explanation or prior practice using the learning system they were assigned.

Participants

Twenty professionals and students from Georgia Tech participated in the study. All of the participants rated themselves as 'very inexperienced' or 'inexperienced' in origami on a background questionnaire. The participants were randomly assigned to one of the two learning systems groups (computer or book) with 10 participants in each group.

Procedure

The participants first completed a background questionnaire to determine their level of experience with origami. Then, using the learning system to which they were assigned, the participants completed three tasks: (1) fold a paper jumping frog, (2) find the term "squash fold," and (3) find the meaning of the word "origami." After completing the three tasks, the participants rated their learning system on a final questionnaire.

Measurements

For each of the three tasks, both speed and accuracy were recorded by the experimenter. The experimenter recorded by hand the actions of the book users while an electronic log file was kept of each of the computer user's actions. The participants also provided subjective measures of the two learning systems by rating their learning system on a final questionnaire.

Results and Discussion

Objective Measures

One-tailed t-tests were conducted on the speed data from all three tasks. On the first task, folding a paper frog, the book users were significantly quicker than the computer users (*book mean = 241.9 sec., computer mean = 384.7 sec,* $p < 0.05$). Although we had hoped that the computer would be more comparable to the book, this result was not surprising for several reasons. First, it takes longer to go through the computer steps, particularly if videos are viewed. It also takes longer for the user to listen to the auditory instructions than it does for a participant to read the instructions. Second, the task was simple enough that the instructions were on only one page of the book. The book users were not required to turn pages to get to the next step, whereas the computer users had to say "next" for the next step. Finally, the book users could look ahead in the instructions, and in some cases did not even read the instructions. This look-ahead ability also helped them to figure out how to make a confusing fold because they could easily compare before and after fold illustrations.

There was not a statistically significant difference between the book and computer users' performance on either of the information location tasks. For the second task, locating the term "squash fold", the book users were slightly quicker (*book mean = 31.6 sec., computer mean = 44.8 sec.*), while for the third task, locating the meaning of "origami", the computer users were slightly faster than the book users (*book mean = 21.7 sec.,* *computer mean = 18.3 sec.).* These were surprising results to us. We expected the computer users to be significantly faster, due to the speed of the computer and not having to turn pages. However, the book was small and participants were very familiar with the typical layout of a book (e.g., table of contents, indexes, and introductions). Also, many of the computer users did not use the "Find" function provided in the computer performance support system. Even though there was a "Find" button on every page of the performance support system, many participants either did not see it or did not think it would help in their current task. In many cases the computer participants fell back on their knowledge of books and would go though the pages of the Origami library. It was while paging through the library section that some users finally noticed the "Find" button. Perhaps the use of a "Find" function makes more sense in a library than in the entire performance support system.

The second objective measure was accuracy of completing the first task, folding a paper jumping frog. Inaccuracies were broken into two categories, those inaccuracies which would have no effect on the final product and those which would affect the final product. Along with inaccuracies, we also computed the ratio of fixed mistakes to total mistakes. The last category was the number of participants who made at least one mistake of either type while completing their frog. It was expected that the computer users' performance would be better in all of these categories (i.e., have a lower number) than the book users' performance due to the ability to look at videos of each step. In all but one case we were correct as shown in Table 1.

Category	Book	Computer
No effect mistakes	7	4
Mistakes with an effect	3	5
Ratio Fixes to Mistakes	10/4 = 2.5	9/5 = 1.8
At least one mistake	7	5

Table 1: Results of accuracy measurements

However, only three participants even used the videos, so it seems unlikely that the ability to see a step done was the reason why computer users made fewer mistakes than book users. Also, two of the people who looked at videos made mistakes. Finally, the computer users made more mistakes that would affect their final outcome than the book users. It appears that more research is needed in this area.

Subjective Measures

There were four, five-point (1=low, 5=high) rating questions on the final questionnaire. The average ratings for the book and the computer are almost identical as shown in Table 2.

Questions - Please rate...	Book	Computer
how much you liked or disliked using the learning system.	3.9	4.1
the effectiveness of the learning system for helping you perform the paper-folding task.	4.3	4.3
the effectiveness of the learning system for helping you to perform the word search tasks.	4.4	4.4
the likelihood that you would want to have this kind of learning system if you had to learn to do paper-folding (origami).	4.2	3.9

Table 2: Results of subjective ratings questionnaire

These results were a little surprising since we thought that the participants would like the computer performance support system better than the book. We were surprised at the high ratings on the book. We thought that the book users might become frustrated and have no way to get around their frustrations since there were no videos. However, it appears as if the task was too simple to take advantage of the video feature of the computer performance support system.

From written comments it appears that the computer users would like the system on a desktop computer but did not enjoy using the head-mounted display. This probably affected their rating of the entire system to some degree.

Conclusion

This initial study highlighted many important issues with the wearable computer performance support system. These issues range from design of the human-computer interface to experimental design. We identified many ways to improve our interface, and offer these as suggestions for future designs of task support software. It is obvious that users fell back on their knowledge of paper books in order to interact with the computer-based system. It would be a good idea to take advantage of this prior knowledge in the interface design. For example, the "Find" button should be labeled "Index". Another possibility is to provide a before and after view of a step in order to confirm that the step was being done correctly. This would provide one function of a video but be much quicker for the user to access. Abilities of the computer system must be clearly marked and noticeable. Neither the "Find" button nor the "Show Video" buttons were used very extensively due to their not being noticed. Perhaps the system should suggest a video after a certain length of time or several requests for repeated instructions.

Wearable performance support systems would seem to be of most benefit to a user when the tasks to be performed are very complex or the environment in which the user must operate prohibits the use of standard materials such as operating manuals. This study did not include these mitigating factors. Consequently, the difference between using the two support systems was minimal. It is encouraging to note in such circumstances that the wearable system did not hinder performance of the user. Future study is planned to verify this hypothesis. Specifically, we will study more complex tasks as well as environmental factors which restrict the use of standard support materials such as books.

Abstract: The purpose of this study is to propose a technical and psychological framework of intelligent computer supported collaborative work/learning (Intelligent CSCW/L) which we call "*iDCLE* (intelligent distributed collaborative learning/working environment)". To realize this learning environment *iDCLE*, we constructed the real-time sharing communication system for collaborative work/learning on the computer network. We describe the mechanism for *iDCLE* which supports group learning intelligently in this paper.
In this paper, we describe the fundamental configuration of *iDCLE*, and discuss the mechanism of supporting discussion. The discussion support system in *iDCLE* can identify the state of discussion by tracing our model. The system can also diagnose the process of discussion for the purpose of making progress in the discussion using this model. If any advice is needed after diagnosing, the system gives the appropriate advice to the participants.

1 Introduction

The systems approach of software development by multimedia/networking communication concerns itself with interaction between the system and its environment in consideration of human and technological factors in the distributed remote sites. Whatever methodology is adopted the systems analyst should be aware of the systems approach. The participative approach involves all those people affected by the new system, encouraging user involvement. Effective technical and human implementations by using computer-based systems like CAD/CASE and distance communication systems like CSCW/CSCL is a new methodology based on the participative approach. From this kind of problem awareness, we suppose necessity of the intelligent networking environment to promote software development.

Recently, the networking technology like INTERNET has been developed rapidly and we can communicate and discuss with others in the distributed environment by such technology. Under such a network environment, we can provide and share the various kinds of the educational information like new teaching methods, educational materials, curriculum contents, evaluation methods and computer using in a classroom with foreign country people. Namely, the educational environment is changing from the closed space to global and the open space.

From those problem concerns, we propose the Intelligent distributed collaborative learning/working environment where people can exchange knowledge and solve the problems through group thinking effectively. Many researchers on educational technology attempt to extend the field of study from stand alone learning environment to group learning environment, where multiple agents interact with each other [Baker94, Baker 95, Blandford 94]. The concept of Computer Supported Collaborative Learning (CSCL) has attracted the interest of many researchers by reason of inspecting human dynamic learning behavior in the real situation. This concept is based on the rationales of knowledge constructivism and social situated learning.

Verbal communication seems to play an important part in collaborative learning under networking environment. Students will solve a problem and acquire domain knowledge, moreover they will improve their self/other-monitoring ability and enhance their group productivity through their discussion process. Thus, it seems how to support the discussion process is one of the most important issues in the researches of CSCL. However, it is difficult for the system to recognize the contents of the utterance from students.

In this study, we constructed the framework of our *iDCLE*, where the participant obtains the educational goal through interaction with each other [Inaba96, Okamoto 95]. We classify the information existing in participants' utterance into two categories. One is concerned with the semantics of the utterance. Another kind of information is concerned with his/her intention for making the utterance. We propose the model of transition on dialogue states with the information related to the intention taken from cognitive experiments. We embed the expert system which plays the role of coordinator to support

discussion based on the model of transition on dialogue states in *iDCLE*. The system with the state transition model can identify a state of discussion, detect some states in which the system should intervene and give some appropriate advice in consideration of each participant's role on discussion process. We had some experiments to evaluate the system's functions of coordinating the flow of discussion. As a result, it was suggested that the system should have the function to identify the state of collaboration among participants.

2 Research Objectives

Our study has three research objectives as follows.

- To construct a dialogue model of discussion on the computer network.
- To develop an intelligent discussion supporting system which can identify the state of discussion and help their discussion by the model described above.
- To construct a model which represents a discussion process for reaching an agreement.

3 The iDCLE System

In this section, we describe the fundamental configuration of *iDCLE*. *iDCLE* is constructed on the UNIX workstations connected by TCP/IP. The core of its graphical user interface (GUI) is constructed on the X11 window systems.

In *iDCLE*, each participant can freely choose either of two workspaces or both. One is the Personal Work Space, which is a closed private area and cannot be referred by others. This enables the participants to explore their individual information and to learn/work something individually as a performance supporting system. The participant can use several tools for problem solving in this space; e.g., a word processor, a drawing tool, an ITS and so on. Another space is the Collaborative Work Space shared by all participants. This space is used to exchange opinions and to solve problems collaboratively. This space has two places, which are called the Communication Channel and the Clear Board.

[Fig.1] shows the learning environment in *iDCLE*. The participants discuss a given task through the Communication Channel. The discussion supporting system including the computer coordinator can identify the state of discussion and give the appropriate advice by tracing the dialogue model. As a result of the discussion, the participants input the answer to the Clear Board. Here, the expert system diagnoses their answers and gives some advice to coordinate group learning appropriately. If the answer is not correct, the participants may discuss again through group learning and change the answer. An example of the Collaborative Work Space in *iDCLE* system is shown in [Fig.2], in which the participants discuss the geometric proof problem solving. The intelligent tutoring system for geometry (we call the *Geomex-Super*) in this case helps participants prove the geometric theorems in the Clear Board.

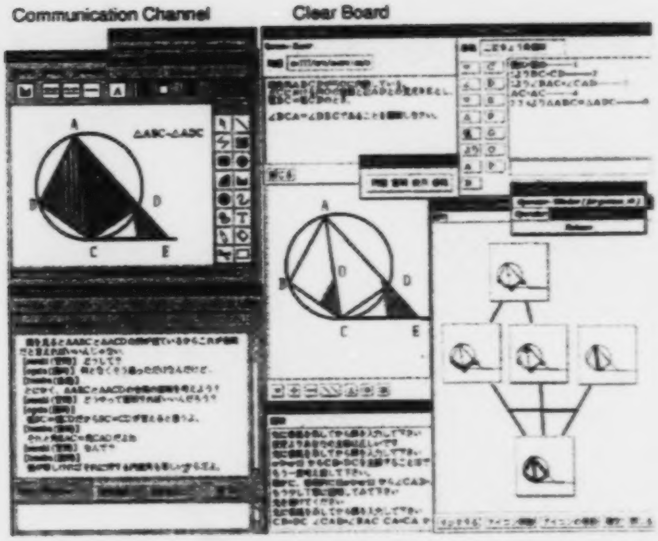

Figure 2: An example of the Collaborative Work Space

The students give their utterance by inputting some sentences to the Communication Channel located on the left side in [Fig.2]. When they finish giving their utterance, they must select their intention from the menu on the Communication Channel. The sequence of inputted intention is stored on working memory in the discussion supporting system. The discussion supporting system diagnoses the state of discussion and identifies a student's role in a discussion process based on the sequence of intention-information on the working memory. Then the system represents appropriate advice on this Communication Channel.

4 Supporting Discussion

As we mentioned above, the discussion on the Communication Channel is supported by the computer coordinator in *iDCLE*. The mechanism of supporting discussion is described in this section.

When each participant makes group discussion about a given problem, the discussion does not necessarily progress smoothly. So a human coordinator gives suitable advice for the state of the discussion process in the real world. For example, when the discussion is progressed by a few participants only, a human coordinator will request another participant, who has not given his/her opinion yet, for something to propose.

We had constructed a discussion support system as a prototype [Okamoto 95]. The system can diagnose four states where the system should intervene. The states are as follows.

- The divergent state of discussion.
- The impasse state of discussion.
- The state in which a participant gives little utterance for a while.
- The state in which a question is not solved.

We had some experiments to evaluate the system's functions of coordinating the flow of discussion. As a result, it was suggested that the system should have the function to identify each participant's role on discussion process. Therefore, we have improved the model of transition on dialogue states and the rule bases on the discussion supporting system which we call the Coordinator system. Next, we discuss the mechanism of coordinating the discussion.

4.1 Model of Dialogue

We propose the model of transition on dialogue states to support group discussion taken from the cognitive experiments. We classify the various kinds of information existing in participants' utterance into two categories. One is concerned with the semantics of the utterance. The information included in this category is related to both the domain knowledge and the context of discussion. Another kind of information is concerned with the participant's intention for making the utterance. Considering a method of supporting discussion, it seems so inevitable that the system utilizes the intention-information included in the participants' utterance to coordinate the discussion flow. We contrived the sophisticated mechanism by which the intention-information can be separated from the contents of a given problem to propose the general purposed framework of *iDCLE*.

The supporting functions of our system are as follows.

- To make users participate actively in the discussion.
- To facilitate group discussion smoothly to the desired direction (such as finding the adequate solution of a problem).

For example, when each participant gives his/her idea and does not say anything related to others' utterance, some advice such as focusing on one issue is needed.

To realize the functions mentioned above, the system should have the function to identify the state of discussion. We classify the participants' intention into ten categories shown in [Tab.1]. We propose the model of transition on dialogue states in consideration of the ten categories described in [Tab.1]. We regard a discussion as the sequential structure of some topics. So, we have only to explore the structure of the transition on dialogue states in a topic. The model of transition on dialogue states consists of four modes: Guide mode, Development mode, Confirmation mode and Query mode. The each structure of four modes is shown in [Fig.3].

The dotted line in [Fig.3] means that there are some conditions to be satisfied for shifting to next state. For example, the condition to shift from S1 to S3 in Development mode is that all students agree with current proposition.

4.2 The model of generating reaction

Satir (1991) suggested a model which represents the internal human process of interaction with the external world. According to this model, a human internal process consists of four elements, that is, intake, meaning, significance and reaction. For information receiving from the external world, a person will interpret the meaning of the information (*i.e.*meaning process), judge the information to be effective in obtaining his/her own goal (*i.e.*significance process) and generate a reaction to the information [Satir91]. However, considering the interaction during a collaborative learning process, a participant will not always decide to accept an opinion when the opinion is effective in obtaining his/her goal. There is a process to decide his/her attitude after the significance process. Here, we propose the model of generating reaction on utterance from other participants in [Fig.4] which consists of three processes.

The participant who receives another person's utterance will enter and succeed in the meaning process and the significance process for the utterance and decide his/her attitude whether he/she will accept it

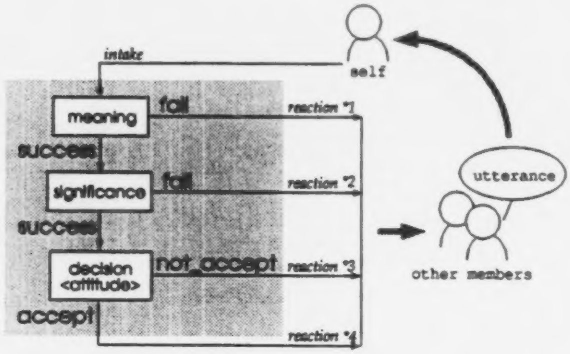
or not in the most simple interaction. The reaction in such case is classified into reaction *3 or *4 in [Fig.4]. When a participant can not follow the other participants, or there is not enough information to understand the other participants' utterance, the participant can not interpret the meaning of another person's utterance, that is, the participant fails the meaning process and generates reaction *1. When a participant asserts his/her opinion without the grounds, the other people may understand what was said, but not judge the information to be effective in obtaining his/her own goal and generates reaction *2.

4.3 The negotiation process

Now, we try to describe the negotiation process using the three processes mentioned above.



intake
self
meaning
fail
reaction *1
success
significance
fail
reaction *2
utterance
success
decision <attitude>
not accept
reaction *3
other members
accept
reaction *4

Figure 4: Model of generating reaction on utterance from others

process	*description*	
meaning	*meaning(Agent, Utterance, State)*	(1)
significance	*significance(Agent, Utterance, State)*	(2)
decision	*attitude(Agent, Utterance, Attitude)*	(3)

The *Agent* means a participant who receives utterance from the other participants, the *Utterance* shows utterance as a target, and the *State* shows whether a participant succeeds a process or not.

We suppose the initial state of the negotiation process requires at least that the participants have the common goal of interaction to attain an agreement. There are not always the beliefs or the goals which are conflicted between the participants. The initial state of the negotiation process may be only absence of the other participants' consent to a proposal. We describe the initial and the final state of the negotiation process as (4) and (5).

state	*description*	
initial state	*negoject(Agent, Utterance)*	(4)
final state	*agree(Utterance)*	(5)

The initial state of the negotiation process is set up as the state in which a participant (*Agent*) offers an proposal (*Utterance*) in order to reach an agreement. We call the proposal which is a target of negotiation "*negoject*". The final state means that the negoject (*Utterance*) is accepted by all participants. That is,

```
agree(Utterance):-
     negoject(Speaker,Utterance),
     attitude(Others,Utterance,accept).
```

The `Speaker` means the proposer of the `Utterance`, and the `Others` means the all participants except for the `Speaker`.

5 Conclusions

In this paper, we proposed the model of transition on dialogue states and the model of generating reaction on utterance from the other participants. We contrived the model of transition on dialogue states which utilizes the intentional information included in participants' utterance. The model has the intelligent functions for diagnosing/coordinating flow of discussion on CSCW/L. We have developed an intelligent communication supporting system for *iDCLE* based on this framework. The expert system, called the Coordinator system, can identify and diagnose the state of discussion using the model of transition on dialogue states, and the system can give some advice suitable for the current state of the discussion process.

Alternative Means of Internet Access: Enabling Financially-Strapped Public Schools

Kevin M. Oliver
Department of Instructional Technology
The University of Georgia, USA
koliver@coe.uga.edu

Lara Luetkehans
Department of Instructional Technology
The University of Georgia, USA
luetke@coe.uga.edu

Abstract: Models for low-cost internet access are being developed through a partnership of universities, public schools, corporations, and local businesses in Georgia. Utilizing microwave technology, internet service is being extended from two universities to one inner-city and one rural school. These technology designs could serve as models for future, statewide initiatives to wire public schools to the internet. While one focus of the project is technological, another is pedagogical. This project also involves university researchers working with public school teachers to develop classroom activities and projects utilizing internet resources. Students will be expected to gather information from the internet to inform the design of real-world scientific experiments and create web pages to describe their findings. Pedagogical goals are to support student efforts at working with the scientific method, help students develop problem-solving and reasoning skills, and provide students with experience in using technology to support their learning.

Introduction

Access to innovative, state-of-the-art instruction need not be restricted by traditional notions of geographic boundaries, curriculum, facilities, or local expertise. Advances in telecommunication technologies and distance learning research and theory make possible teaching and learning opportunities that are currently unavailable in all but a few live, site-based learning environments. With high speed networking technologies and advanced telecommunications becoming interactive through two-way carrier technology, learning at a distance is being transformed.

A research project utilizing the instructional experience and technical expertise of three major universities (The University of Georgia, Clark-Atlanta University, and The Georgia Technological Institute), the funding of the Georgia Research Alliance (GRA) and AT&T, and the support of local businesses (e.g., cable, communications) is underway in the state of Georgia. Referred to as "Science Connections: Problem Solving at a Distance," this project aims to demonstrate new, low cost solutions to accessing the internet for public schools. Improved access alone, however, is insufficient. Significant advances have been made, not only in the ability to transmit data and images, but in developing distance learning environments that are based on emerging theories in teaching and learning. Contemporary perspectives emphasize authentic learning environments as individuals develop an understanding of content as well as metacognitive skills to support and transfer learning for other tasks. The focus of this project is therefore both technological and pedagogical. Two test sites have been identified and are being linked to the internet for this demonstration project: a high school in urban Atlanta and a middle school in rural Georgia.

Technological Barriers and Solutions

Currently, schools in Georgia and across the United States and Canada are struggling to "wire" their classrooms and media centers to the internet. Expensive T-1 lines and fiber optic cabling are simply too cost-prohibitive for public schools with limited technology budgets. In an effort to remedy this problem, it is possible to employ new technologies, and some old ones, that serve the same purpose as expensive hard-wiring.

Providing schools with non-traditional access to the internet is not the key problem for this project. A number of solutions are available which simply provide access. For instance, internet resources can be provided to schools at high speeds by employing existing cable and phone lines. Further, small satellite dishes using Direct Broadcast Satellite (DBS) technology can be used by schools to receive internet data-transmissions in addition to audio-visual programming. Schools can sign-on to internet service providers and access the internet via slow-speed modems.

This project seeks not only to provide schools with access to the internet, but also to allow teachers and students to produce and generate their own products, serving and sharing them with a world-wide audience. While receiving internet information is not a problem, allowing schools to serve their own materials to the internet is more difficult. Depending on cable access, proximity to universities, topography, and a variety of other factors, different classes of solutions can be enacted to give schools both in and out internet connections. For instance, urban schools with cable or fiber connections can both access and serve internet resources at low-cost. Urban schools and rural schools without these connections, however, must rely on other solutions such as microwave technology to both access and serve internet resources.

Clark-Atlanta, Inner-City Technology Model

The technology design team at the Georgia Center for Advanced Telecommunications Technology originally planned to make use of the existing infrastructure at Washington High School (i.e., reverse path coaxial cable) to establish an internet link downstream from Clark-Atlanta University and upstream from Washington High School. However, cable companies providing service to the Washington High School area are not offering two-way internet service at this time. They are in a transitional phase, planning for future services, so the original plan to use cable reverse path technology did not fit within the time frame of this project. Current plans are to establish a microwave connection between Clark-Atlanta University and the high school as outlined below.

University of Georgia, Rural Technology Model

Without an existing infrastructure of cable wiring, the rural Oglethorpe Middle School technology model involves a wireless microwave link between a communications tower near the school and the University of Georgia. The school currently uses dial-in modems to reach the internet at a speed of .25 megabits per second. The microwave link will speed up the rate at which students can access and download resources by 8 to 16 times–2 to 4 megabits per second. An Aironet 2Mbps long range wireless ethernet bridge has been purchased and will be placed atop the University of Georgia library. This will convert data signals from the library's network into microwave signals that are sent over a 21dBi solid dish antenna to the communications tower near Oglethorpe Middle School. Another solid dish antenna and ethernet bridge will reside on that tower to receive and decode the microwave signals. To get this signal into the school, two options are being considered. First, hard wiring a short line between the tower and school are possible using either 10 Base 2 coaxial cable or 10 Base T twisted pair cable, depending on the school's current intranet network configuration. 10 Base 2 is easier to install but can lead to internal troubles (e.g., if one person disconnects from the network, occasionally the entire network can go off-line). 10 Base T involves wiring each computer separately from the school network hub, however troubleshooting becomes much easier when one computer goes down. The second option for transmitting the data signal from the tower to the school is to purchase two additional dishes to establish a wireless hop.

Why Use Wireless?

The disadvantages of using wireless signal transmission include: it is more costly to install than a T-1 line in terms of equipment; establishing the necessary line of sight may entail placing equipment on towers or tall buildings; weather conditions can slow data rate transfer; and the farther the school is from the originating site, the more the data signal is degraded. These are properties of the Aironet long range wireless ethernet bridge being purchased for the Oglethorpe Middle School connection.

Advantages of using wireless transmission include: schools avoid costly monthly fees to internet service providers, thus the system is more cost-effective than T-1 lines over time; the system is controlled by educational institutions, not an external agency or company (i.e., cable company); and, there is no need to wire an infrastructure, dig trenches, lay fiber or co/ax cable, or obtain public right-of-way. Monthly service fees for schools opting to install a T-1 line currently range from $600 to $2000 per month. Rural areas can expect to pay higher fees. Installation costs for a T-1 may run near $2000. The in-house wireless system for Oglethorpe Middle School has been purchased for a one-time fee of $12,000, with the understanding that the school will get internet access for free through the University of Georgia, a communications company near the school will provide free space on its tower to establish direct line-of-sight requirements, and installation of the system will be free to parties involved through the Georgia Center for Advanced Telecommunications Technology (GCATT). Through collaboration, a relatively low-cost solution has been afforded to one school which may serve as a model for future state efforts at wiring other schools, particularly in rural areas.

Home Access

Establishing internet access for students at home is considered a key component of this project. Once again, the goal is to test low-cost solutions that can be enacted on a state and local level rather than experimenting with high-cost, state-of-the-art technologies. Cable television companies typically set up many cable head ends around large cities and smaller markets–examples include airport channels and community access channels. For this project, a no-cost agreement has been reached between local cable companies and the public schools to turn school video studios into a cable head end. Once again, line-of-sight microwave signals will be used and will be transmitted via a satellite dish from the school to the cable company. The cable company will broadcast student video programs and/or internet signals over a community access channel at agreed upon times. This creates a downstream link from the internet into students' and teachers' homes. To make all of this happen, students and teachers at home will utilize a GCATT device known as the "telemouse" to communicate computer commands back to the internet browser located at the school. The current version of the telemouse includes a keyboard and mouse which plug into a modulating box. Students dial in to a school telephone line which connects their telemouse to an internet-ready computer. As students search web pages, the video signal is transmitted to the cable company which comes into students' homes over standard cable wiring. The cost of each telemouse device is approximately $50, priced comparatively near a library book. Students at each school will likely check out and be responsible for this equipment during the term in which their classes utilize the internet. Two concerns emerge from this model. First, only one student at a time can access the internet from home, and these interactions can be viewed by anyone with access to that cable channel. Second, although cable penetration is quite high, there may be some students without cable tv who will be denied the benefits of home access.

Those involved with the project are already considering new models of instruction that this system may afford. By placing certain groupware programs on the school computer transmitting signals to the community, it is possible for a teacher to get on-line from home and send his or her voice and image over the cable system to students and parents at home. Groupware products will not only allow an individual to be seen and heard, but will also allow students to work on written documents together, or to demonstrate their work to an extended audience. The enhanced techniques and increased reach truly define one model for moving the school from "behind closed doors" into the community at large.

Resource Sharing

Programming time on cable tv, equipment, and physical space on a communication tower are examples of free services and technology being offered by local businesses to sustain a low-cost model of internet access for this project. Businesses across the state (e.g., cellular, cable, network tv) see this sharing of resources as a profitable approach as they usually must pay for land to put up towers. In the future, schools might lease property to these businesses for free in exchange for space on their towers. Experimenting with connectivity possibilities at test sites should help inform the feasibility of new approaches like microwave technology for the schools and internet access equipment for students at home.

Increased Support for Contemporary Models of Learning

Providing public schools with access to technological resources is an important step, but there is still a need to consider pedagogical issues, instructional design, and the eventual manipulation of these resources. Just as a set of encyclopedias has never been a curriculum, a low-cost internet connection will not instantly revitalize public education. By developing a technical infrastructure for our public schools, however, we are enabling teachers with technology and access to resources which will support contemporary models of learning. These new models often establish learning environments or dynamic systems where students learn through experience rather than compliance, manipulate rather than memorize, and hypothesize rather than tacitly accept.

The capacity to set up problem-based learning environments via the internet is encouraged through this project. Internet environments with a problem-based focus afford several benefits over traditional instructional methods in teaching science, including:

1) establishing support for discussion among students and instructors through synchronous communication,
2) creating a mechanism for accessing new information and external resources,
3) providing a mechanism for collaboration on products and/or shared work space,
4) developing a mechanism or strategies to provide experiential opportunities for the learners, and,
5) creating a mechanism to provide training and mentoring.

A goal of this project is to move students toward scientific literacy. We suggest a number of measures here which will support students in the investigative or scientific reasoning process as they work in technologically-enhanced schools. These stages emanate from the problem-based learning process as defined by [Barrows 1995] as well as the network science model outlined by [Feldman & McWilliams 1995] at TERC. Overall features include:

1) group communications: students can post to a group, other individuals, or a classroom facilitator via e-mail; and, real-time conferencing is possible as needs arise during resolution of scientific problems;
2) links to internet resources, multimedia databases, and other authentic information sources used in gathering and analyzing information during scientific problem resolution;
3) on-line simulations or games that introduce problems and guide students through the investigative process;
4) examples of completed problems or documents by previous students who have resolved a problem
5) the presentation of problems that contain less scaffolding for the students and require them to facilitate problem resolution; and,
6) document creating and sharing.

Science Education, Curriculum Planning

Science education is at a critical point. It is becoming explicitly more evident for all people to become science literate. As citizens are being required to make decisions on environmental issues, consumer products, etc., it is important that they have an understanding of the process of science and its impact on society. Only 20% of the

U.S. population has the knowledge to be considered scientifically literate [Gallagher, Stepien, Sher & Workman 1995]. It has also been determined in a study by [Miller 1989] that pre-college learning does not contribute significantly to developing scientific literacy.

Scientific literacy as defined in this project is an awareness of the problem solving process including the abilities to make qualitative judgments about what science offers to society and the perspectives from which it comes. Currently K-12 science curricula are based on a foundation of established facts. This does not model what occurs in the question-centered, collaborative practice of scientists [CoVis 1995]. There is an increased need to move science education toward obtaining proficiency in the scientific, problem-solving process, and this project is exploring how innovations in technology and pedagogy can be used to meet the needs of today's pre-college science literacy curricula.

Scientists at The University of Georgia and Clark-Atlanta University have volunteered their time to work with teachers on this collaborative project. Together, they are discussing appropriate design and implementation measures and are developing problem-based curriculum plans that will make use of the new technological infrastructure. Such partnerships between the "ivory tower" and the school "trenches" allow university researchers to study novel approaches to teaching and learning while assisting teachers with their questions and concerns as they attempt to integrate technology in the classroom.

Some of the questions under consideration by the teacher-researcher collaborative teams include: what strategies and technological features will enable problem-based learning environments, how do teachers and students communicate in problem-solving activities, and what types of communication and/or activities might be best delivered in a distributed environment that includes the home?

One scientist, [Hagen 1996], describes his vision of the curriculum:

> I envision teachers, students, and parents using the tools we are creating for the AT&T project in a location and time independent fashion as needed to complete their class projects. I would like the classroom to be like a short business or research group meeting with teachers and students then spending most of their time working on their respective projects. I envision our support tools being on a server. It would serve the tools and their content, rich data sets for student projects, connections to specialized research instruments or software, have links to relevant on-line information resources, and communication/collaboration tools. I see teachers interacting with each other, students, parents, and outside experts and also students interacting with each other, teachers, parents, and outside experts. Some but not all of this could be on an in-school server, but it would be much better to have robust connections beyond the school to homes, libraries, universities, etc.

Two instructors working with the project have chosen to modify an existing lesson plan to meet both state and local curriculum requirements as well as goals of the project. The lesson "Consumer Fair" encourages students to develop process skills as they design experiments which test products. The main purpose is to help students understand the variables involved in designing scientific experiments and to use the scientific method in carrying out those experiments. Students are to bring in low-cost materials from home to conduct their experiments. They may ask such questions as, "which diaper holds the most water," or "which popcorn pops the best?" Teachers will assess students according to the background information they use to inform their hypotheses and questions, their creativity in experimental design and presentation, and their organization and clarity of argumentation when reporting overall findings. The internet connection will assist students in gathering information, communicating with experts, and eventually publishing those results in the form of web pages. To maximize their short class time, teachers will not allow students to randomly browse the internet during regularly scheduled school hours. While some gathering of information may take place in the classroom, most class time will be reserved for discussion, experimentation, and development of final reports in the form of web pages. Once students select a topic, they will be able to conduct background research and gather information from the internet at home using the telemouse equipment. Teachers will also be involved in gathering resources for students, using their home access equipment.

Future Plans

An evaluation plan is being developed for teachers and researchers involved with the project to collect information. The focus will be on the influence of the developed infrastructure as well as the applied problem-based curriculum during a two-week demonstration period in May, 1997. Updates and results on "Science Connections: Problem Solving at a Distance" can be obtained at the following World Wide Web site: http://lpsl.coe.uga.edu/projects.html. Finally, with the technical infrastructure in place, these schools will serve as test beds for future collaborative research efforts between teachers and university researchers.

Abstract: Internet information sources are proliferating at an astonishing rate, however much of that information is of dubious or unknown quality. Educators are in need of instruments to assist in evaluating information quality, which is the goal of a project underway at The University of Georgia. Indicators of information and web site quality have been identified, classified within eleven criterion categories, and rated in terms of importance by a panel of experts on Internet resources. The highest rated indicators of information quality will provide the framework for a set of instruments and procedures for the evaluation of Internet information resources. Along with the information quality indicators, highly rated indicators of site quality will be used to provide design guidelines for the developers of Internet information resources.

Introduction

Internet resources, in particular World Wide Web resources, continue to proliferate at an astonishing rate. A great deal of information is posted to the world every day, but unfortunately very little is of high quality. Unlike professional journals and commercial publishers, who employ a system of editorial review and external referees to ensure the caliber of materials distributed, information can be spread over the Internet by anyone without regard to accuracy, validity, or bias. Due to its global structure, which encompasses a variety of legal systems and cultures, it is unlikely any one individual or nation will be able to significantly influence, regulate, or change the chaotic state of flux that characterizes the World Wide Web. As indicated by a content analysis conducted by [Debashis 1995], much of the material posted on the Internet is self-promotional or commercial (21.9% public relations and 20.7% advertising).

The low quality level and the need to carefully evaluate electronic information has been alluded to by several authors [Descy 1997] [Fitzgerald 1997]. Some groups claim to be rating the "quality" of Internet information (e.g., Point Communications' Top 5% of the Web, and Magellan's Star Ratings Systems). Typically, these focus on such indicators of "quality" as how "fun" or "entertaining" a web site appears to be, rather than the instructional value or validity of the content within that site. A need exists for criteria and procedures that will assist students, teachers, and other users in evaluating the quality of Internet information and for standards to guide the design of web resources. This paper is a progress report on a project that was established to develop such a set of criteria and standards. The project is being conducted in six phases, as described below:

Phase One: Identification of Possible Criteria

Phase one dealt with the identification of possible criteria that could be used to evaluate the quality of Internet information. A number of sources were consulted to extract this information. Among these were (1) compilers of highly rated resource lists, (2) periodicals, journals, and published indexes dealing with Internet resources, (3) on-line rating services, and (4) authorities on library reference materials and processes.

The most valuable sources of information were compilers of Internet resource lists. Individuals or groups that actively maintain listings of Internet resources on a variety of topics (e.g. engineering, science education, cooking) were identified from the listing maintained by The University of Michigan's [Clearinghouse for Subject-Oriented Internet Resource Guides 1996], now the Argus Clearinghouse, which evaluates Internet resource lists. The compilers of lists, which were given high marks for resource evaluation by the Clearinghouse and which were being actively maintained, were contacted via e-mail and asked to describe the criteria they used for selecting resources. Of 43 compilers contacted, 36 responded to the e-mail, and 24 provided selection criteria. A total of 147 suggested criteria or quality indicators were provided by the list compilers.

To identify further criteria of information quality, we consulted a variety of periodicals, journals, and published indices that suggested or rated Internet resources, including *Wired*, *NetGuide*, *The Internet Yellow Pages*, and *The Net*. In addition, the web sites of on-line rating services that provided evaluations of Internet sites were consulted. Typically, these publications and groups did not list selection criteria for the resources they chose to highlight. Those that stated any criteria at all typically focused on vague characteristics of resources such as "well executed," "hip," or "innovative." Such criteria have little to do with the information quality of a resource. Criteria such as "purpose," "coverage," "currency," and "accuracy" are better suited to select and recommend Internet resources. Such criteria provide a standard by which to measure the information quality of an Internet resource. Criteria of this type were more commonly located within the literature on library reference source evaluation [Katz 1992] [Bopp & Smith 1991] and the literature on instructional/web site design than from popular press Internet magazines and on-line rating services. Using such sources, an additional 362 items were identified to produce a total listing of 509 possible criteria or indicators of quality.

Phase Two: Editing and Consolidation of Criteria

Phase two dealt with the editing and consolidation of criteria. A content analysis was conducted on the 509 original items to eliminate duplicate items and clarify those with ambiguous meaning. Any items that were meaningless or which could not be operationally defined, such as "I pick the good stuff," were eliminated. Through this process, the original listing was reduced to a total of 125 indicators of resource quality. The 125 indicators were categorized under eleven major criteria. The major criteria along with the number of indicators within each of the criteria categories are listed below in Table One. Definitions of the criteria as well as a complete listing of the 125 indicators of quality have been published in the May/June, 1997, issue of *Educational Technology* [Wilkinson, Bennett & Oliver 1997].

Phase Three: Evaluation of Consolidated Criteria

Some of the indicators identified in phase two seemed to deal more with aspects of the web site than with the quality of the information provided by the web site. Also, 125 indicators were too many to be of practical use by resource evaluators. Therefore, phase three of the project sought to use the opinions of experienced Internet resource users to identify the focus and assign a rating of importance to each of the indicators. Of the 36 compilers of highly rated resource lists responding to our call for evaluation criteria, 30 had agreed to serve on a panel to rate the criteria that were developed. Since the Argus Clearinghouse continually evaluates lists and adds new resource lists to its on-line database, we were able to identify an additional 61 compilers of Internet resource lists that were highly rated on resource evaluation. These individuals, along with 13 compilers who had not responded to the initial invitation, were invited to join the review panel for phase three of the project. Of these, 34 agreed to join the panel, creating a total of 64 compilers who agreed to review the list of quality indicators.

A questionnaire was developed that asked panel members to identify whether each of the 125 items was an indicator of information quality, an indicator of web site quality, or an indicator of both and to rate the importance of each criteria on a six point scale ranging from irrelevant (1) to essential (6). The panel was also encouraged to provide comments and suggestions related to the criteria categories as well as the individual indicators. To collect this information, two versions of the questionnaire were created--one web-based and the other on paper. Copies of these instruments are available for examination through the project's web site [Wilkinson, Oliver & Bennett 1997]. 34 of the panel members were mailed paper copies of the questionnaire along with pre-paid return envelopes and the remaining 30 members were mailed letters inviting them to link onto the web-based questionnaire. One month after the initial mailing, the panel members who had not responded were contacted by e-mail and offered the alternative versions of the questionnaire.

Of the 64 panel members who had agreed to participate in phase three, 49 completed the questionnaire for an overall return rate of 76.56%. 28 paper questionnaires (82.35%) were completed and returned while 21 panel members (69.9%) completed the web-based questionnaire. The lower return rate for the web-based questionnaire, despite the perceived ease of using such forms and the Internet access and familiarity of the panel members is an interesting question for further research. Demographics of the responding panel members include the following: 75% male, 25% female; equally dispersed in age from 18-58; 73% work within higher education, 13% in business/industry, with just a few in government or k-12 school setting; and 40% were specialists in the library and information science field, 36% in an academic subject field, and 13.3% came from computer science/technology.

Although each of the indicators was felt to deal with some aspect of the quality of the Internet resources that were located, some of them dealt with the information while others appeared to deal more with the quality of the site or the experience of using the site. Responses to the first question following each indicator were used to classify the indicator as dealing primarily with the site, the information within the site, or with both site and information. If fifty percent or more of the panelists indicated that the item either dealt with site or with both site and information, it was classified as an indicator of site quality. If a similar percentage felt the item dealt with information or both site and information, it was classified as an indicator of information quality. As a result, a total of 45 of the 125 indicators were categorized as dealing with both site and information quality. The other 80 indicators were divided between site and information to produce the distribution within criterion categories as shown in Table One below. As can be seen in Table One, a few of the criteria categories, such as "Site Access and Usability" and "Aesthetic and Affective Aspects," deal primarily with the quality of the web site while a number of the other criteria categories deal entirely with the quality of the information within the site.

	Number of Indicators		
	Total	**Site**	**Information**
Criterion 1: Site Access and Usability	18	18	2
Criterion 2: Resource Identification and Documentation	13	4	13
Criterion 3: Author Identification	9	3	9
Criterion 4: Authority of Author	5	–	5
Criterion 5: Information Structure and Design	19	13	19
Criterion 6: Relevance and Scope of Content	6	–	6
Criterion 7: Validity of Content	9	–	9
Criterion 8: Accuracy and Balance of Content	8	–	8
Criterion 9: Navigation within Document	12	12	8
Criterion 10: Quality of the Links	13	10	12
Criterion 11: Aesthetic and Affective Aspects	13	13	6
TOTAL	**125**	**73**	**97**

Table 1. Classification of Indicators by Criterion Category

In addition to indicating the focus of each of the quality indicators, the panelists were asked to rate the importance of the indicator on a six point scale so that the more important items could be identified for inclusion in the evaluation instruments. Because individuals might be ranking items differently depending on whether they were thinking of the item as dealing with the site or with the information within the site, a mean value was computed for those who felt the item dealt with information quality and a different mean value was computed for those who felt the item dealt with site quality. The rank and mean value assigned to each indicator for information quality (those rated as important or essential) is presented in Table Two below. Values for site quality are presented in Table Three. The effects of classifying the indicators on the basis of the percentage of panelists who regard the item as dealing with site or information is born out by the fact that eight of the nine highest rated site indicators was dropped from the final list when the criteria was set at 50 percent for inclusion in the ranked listing. Using a 50 percent cut off, the total number of information quality indicators was 71 and total of site quality indicators was 67.

Rank	Mean	Indicator	
1	5.60	**9.1**	Is there a good organizational scheme (e.g., by subject, format, audience, chronology, geography, authors, etc.)?
2	5.37	**6.2**	Is the information sufficiently current to meet the user's needs?
3	5.35	**8.1**	Are there any obvious errors or misleading omissions in the document?
4	5.33	**10.10**	Are the links relevant and appropriate to the document?
5	5.32	**3.1**	What is the author's name?
6	5.29	**3.2**	What is the author's professional or institutional affiliation?
7	5.28	**8.5**	Does the author or the sponsor of the site have a vested or commercial interest in the topic?
8	5.27	**10.8**	Are the links evaluated in any way prior to inclusion?
9	5.19	**2.10**	When was the document last revised?
10	5.15	**2.1**	What is the title of the document?
11	5.09	**2.2**	Within what major fields, disciplines, or topics does the document fall?
12	5.07	**5.5**	Does the content fit the stated scope, purpose, and audience?
13	5.05	**6.1**	Is the content related to the user's needs?
14	5.03	**5.1**	Is the scope of the document clearly stated?
15	5.02	**4.1**	Is the author a recognized authority on the topic of the document?
16	5.00	**8.3**	If the document deals with controversial issues, is the bias of the author clearly identified?
	5.00	**7.6**	Does the author provide a bibliography or cite references to confirm the accuracy of the information?
18	4.97	**5.3**	Is the title of the document descriptive of its content?
19	4.93	**8.4**	Is the site sponsored or cosponsored by an individual or group that has an established position regarding the issues discussed in the document?
20	4.91	**2.5**	Is there a description of the document's content?
	4.91	**5.6**	Does the use of graphics and icons contribute to the clarity and usability of the information?
22	4.90	**2.3**	For what audience was the document designed?
23	4.89	**1.2**	What individual, group, or organization sponsors and/or maintains the site?
24	4.88	**2.4**	What is the mission, purpose, or scope of the document?
	4.88	**10.9**	What are the link selection criteria, if any?
26	4.85	**6.5**	Are there any obvious gaps or omissions in the coverage of the topic?
	4.85	**9.2**	Is there provision for topic narrowing via conventions such as menus that follow the organizational scheme?
	4.85	**5.4**	Does the content fit the stated scope, purpose, and audience?
29	4.82	**3.4**	What is the author's training or experience with the topic?
30	4.76	**8.7**	Is the information presented in the document of a consistent quality?
		6.3	Is the coverage of the topic sufficiently broad to meet the user's needs?
32	4.74	**4.5**	Is the author affiliated with an educational institution, research laboratory, governmental agency, or other reputable organization related to the topic of the document?
	4.74	**2.7**	When was the document created?
34	4.70	**3.9**	Was the development of the document funded or otherwise supported by an individual, group, or organization other than the identified author?
	4.70	**4.4**	Is the author's experience appropriate and related to the topic of the document?
	4.70	**7.7**	Does the author provide verifiable statistics to support conclusions?

Table 2. Highest Rated Indicators of Information Quality

BEST COPY AVAILABLE

Rank	Mean	Indicator	
1	5.60	**9.1**	Is there a good organizational scheme (e.g., by subject, format, audience, chronology, geography, authors, etc.)?
2	5.34	**11.9**	Is the design so complex that it detracts from the content?
3	5.22	**11.3**	Are readability and legibility guidelines followed (e.g., sufficient color and tone contrast between text and background, font size, doesn't use all caps, etc.)?
4	5.05	**10.1**	Are the links clearly visible and understandable?
5	4.97	**9.7**	Is there a consistent sense of context or understanding of position within the document at any given time?
6	4.94	**5.6**	Does the use of graphics and icons contribute to the clarity and usability of the information?
7	4.91	**2.13**	What is the URL of the document?
8	4.88	**10.13**	How reliable are the links (are there inactive links or references to sites that have moved)?
	4.88	**1.2**	What individual, group, or organization sponsors and/or maintains the site?
10	4.85	**1.12**	Is it a commercial site that requires payment for full access?
11	4.81	**9.5**	Is there a table of contents that can be used to navigate within the document?
12	4.80	**9.4**	Is there an index that can be used to navigate within the document?
13	4.79	**9.2**	Is there provision for topic narrowing via conventions such as menus that follow the organizational scheme?
	4.79	**10.2**	Do essential instructions appear before links and other interactive portions?
15	4.77	**2.12**	If the resource is to be removed, does the site state where it will be available?
16	4.75	**11.1**	Does the document follow accepted graphic design principles (e.g., balance, unity, proportion, simplicity, etc.)?
17	4.73	**1.13**	If commercial, is the price specified up-front?
	4.73	**1.1**	What is the name of the site?
19	4.72	**11.5**	Do the creative elements enhance the usability and appeal of the document?
20	4.68	**1.10**	Is it usually possible to reach the site, or is it frequently overloaded or shut down?
21	4.65	**1.17**	If involving confidential information, are interactions secured?
	4.65	**11.2**	Does the document follow accepted text design principles (e.g., appropriate use of headers, limited mix of type styles and sizes, etc.)?
23	4.64	**10.4**	Are links annotated?
24	4.63	**11.8**	Does the interface make use of consistent menu conventions from screen to screen (e.g., terminology, icons, positioning on page, etc.)?
25	4.58	**9.8**	If linking to another page, is there a way to get back to the home page?
	4.58	**10.5**	Are users informed of the type of file they are linking to (e.g., video, sound, etc.)?
27	4.56	**2.6**	Is the user informed of improper or controversial materials (e.g., adult language, sexually explicit material, gratuitous violence, etc.) within the document?
28	4.52	**5.8**	Does the site offer a variety of features in addition to delivering content (e.g., provides e-mail links for further information, downloads, ordering, discussion lists)?
29	4.50	**1.7**	Is the document source code free of bugs and breaks?
30	4.49	**9.9**	Is it easy to locate a particular page from any other page?

Table 3. Highest Rated Indicators of Site Quality

Phase Four: Development of Evaluation Instruments and Procedures

During the Spring of 1997, the information developed during phase three of the project will be used to develop products in two major areas:

(1) The quality indicators that received marks near "essential" and which were classified as related to information quality will be used as the framework for the development of instruments to evaluate the quality of resources

located on the Internet. At the same time, procedures and strategies for effective searching for resources and for the application of the evaluation instruments will be developed.

(2) The criteria that were identified by the panel as being related to site quality and which received high importance ratings will be used to develop a set of guidelines for the development of quality web sites. These guidelines will then be used to develop templates for web site design.

The development of the different products will of necessity require some cross matching of indicator categories. For example, in order to determine the bias of vested interest of sponsoring bodies (information quality items #8 and #23) it will be necessary to identify the sponsor of the site (an item in Criterion 1 that was classified as a site indicator). Also, the web site design guidelines will need to contain the indicators necessary to make judgments about the quality of the information.

Phase Five: Field Testing and Validation

During phase five, the resource evaluation instruments and procedures developed in phase four will undergo a formative evaluation process with a population of undergraduate pre-service teacher training classes at The University of Georgia. These future teachers are representative of young learners that have been underexposed to evaluation and selection processes--especially of the dynamic and varied content accessible through the Internet. They also represent the models for more naive, younger k-12 learners who will depend on them to select quality resources or to scaffold strategic steps in searching for and retrieving on-line information. The final versions of the instruments will then be used by graduate students to assess the quality of representative samples of Internet resources within various subject areas.

Phase Six: Dissemination of Products

Following validation, information about the instruments and procedures will be disseminated by means of journal articles and conference presentations. The actual instruments and procedures will be made available, at no charge, through the project web site at The University of Georgia: http://itech1.coe.uga.edu/Faculty/gwilkinson/ webeval.html. Until the instruments have completed field testing, this site will contain continuing updates on the progress of the project.

Abstract: This paper describes a study in which a WWW learning environment was created using socio-constructivist instructional design principles. A qualitative research method was used to investigate the learning behaviours of classroom-based students in this instructional setting. In particular the study sought to investigate collaborative learner behaviours in settings where the instructional materials involved open-ended investigations and learner support by means of a printed guide. Observations of student behaviours provided little to confirm our contentions that such environments will create an instructional setting which encourages cooperation, reflection and articulation among students.

Introduction

There is growing interest in higher education about the use of the World Wide Web (WWW) as a learning tool. The WWW enables the development of powerful information sources to support learning and facilitates student-centred instruction [Becker & Dwyer 1994]. It supports and encourages exploration and inquiry, behaviours that are frequently associated with enhanced learning outcomes. However providing students with access to such meaningful content does not always guarantee learning. Contemporary learning theories indicate that learning is achieved through a process of knowledge construction [eg. Reeves 1993]. When a learner is confronted with new knowledge, the learner's intentions, previous experiences, and metacognitive strategies are all essential elements in determining what becomes of the knowledge. The effectiveness in any learning environment is based upon the types and levels of cognitive and metacognitive activity engendered in the learners. It is now widely accepted that learning is enhanced in instructional settings where students are engaged in processing personally relevant content and are reflective during the learning process [Jonassen 1994]. The use of collaborative learning environments seems a natural way to create such settings. This paper describes a study which was conducted to investigate the potential of a collaborative WWW-based learning environment.

Learning Through the WWW

There are a number of learning theories which can been used to describe the nature of learning in WWW and other multimedia environments. In our previous research we have been guided successfully by the theories of situated learning [Brown, Collins & Duguid 1989], social-cognition [Vygotsky 1978] and conversation [Laurillard 1995]. Such theories apply and extend information processing and constructivist learning ideas in ways which are well suited and potentially very powerful in higher education learning environments. Interest in social-cognitive theories and in social-constructivism has been fuelled in part by a growing awareness of weaknesses in information processing and constructivist approaches to describing learning [Prawat & Floden 1994]. Talk and discourse have long been seen as critical components of the learning process. [Vygotsky 1978] argues that learning is frequently achieved through interactions supported by talk and that language and talk are frequently associated with the development of higher order learning. Higher-order learning is achieved when students are confronted by tasks which lead them into cognitive conflict and resolution. Dialogue and discourse enables and encourages this form of cognitive activity by providing a context and means for explaining, justifying and acquiring reasoning skills.

The learning value of language and discourse is acknowledged as one of the main reasons for the popularity and instructional effectiveness of collaborative learning environments. Collaborative learning is consistently used by teachers in elementary and secondary schools and continually returns significant achievement gains. These gains are usually attributed to the complementary effects of motivational and cognitive factors. The motivating factors encourage students to work towards common goals in cohesive groups where the interests and achievements of all learners are important. The cognitive gains are derived from developmental perspectives associated with children's social interactions, and resulting cognitive restructuring and elaboration brought about by the discourse and dialogue [Damon 1984]. Currently much of the teaching and learning in higher education associated with computer-based delivery is planned for individuals learning independently with computers. There appear many advantages to be gained from a move to more collaborative and cooperative learning environments.

[Slavin 1996] describes a number of strategies which have been found to enhance and encourage cooperation and collaboration in small group settings. Some of the strategies described include: developing investigative and controversial tasks without single answers to encourage articulation, discussion, and debate among learners; creating group goals for learning tasks which promote collaboration and individual accountability; and providing strategies and support to promote and aid interactions between learners. [Pilkington & Parker-Jones 1996] suggest the need in collaborative environments for pairing students with symmetrical roles to encourage them to argue and to prompt reasoning. [Palincsar & Brown 1984] describe the valuable role of tutor scaffolding to help develop dialogue strategies, and the consequent withdrawal leaving learners to generate their own discourse.

There are many forms of supports for collaborative learning although in higher education, some appear to hold stronger prospects than others. Adult learners tend to show high levels of self regulation and self-motivation in their approach to learning. In group situations, the better supports appear to those which provide a context and method for collaboration. In this project we chose to investigate the potential of the use of investigative activities and scaffolding devices as instructional supports for collaborative WWW learning. Our intention was to examine the ways in which WWW materials with open-ended inquiry based activities and support materials supported and encouraged collaborative activities, and to examine the forms of interaction and collaboration that resulted to see if these attributes influenced students' levels of cognitive processing and engagement.

Methodology

We chose a module from a local course, Multimedia Networking and Communications, for this study. A lesson was planned for a component of the course where use of the WWW as an instructional tool would be most appropriate. A WWW-based document, *Designing Home Pages*, was developed which was intended to assist students to develop a knowledge and understanding of the use and design of home pages. We created a WWW-based instructional episode that incorporated the lesson content supported by a number of open-ended and inquiry-based activities. The document comprised four chapters, each of which contained a textual description of the topic, links to relevant sites, a learning activity and a series of quiz questions. Each chapter of the document contained approximately 500 -750 words of text, 20-30 images of sample home page designs and elements, and 15-20 links to relevant WWW documents and sites.

This study was part of a larger research project research conducted among 58 university students. The component involved six students, working in three pairs across three different laboratory sessions. The students completed their learning activity on a computer with special data gathering devices attached. A small camera above the computer was used to gain and audio and video record of student interactions and this image was recorded as a window on a larger image of the display from their computer. These images provided a video recording which enabled us to see how students were behaving, to listen to what they were saying and to view the screen images with which they were working. Transcriptions were made of the discussion and exchanges between the students in each of the three groups. The interactions and exchanges between the students were tabulated and classified.

In our previous studies of learner interactions in telecommunication supported learning environments [Oliver & McLoughlin in press], we have used a set of 4 dimensions developed from [Henri 1992], namely social, procedural, expository and cognitive. More recently [Pilkington & Parker-Jones 1996] describe the DISCOUNT analysis scheme for analysing learner dialogue in collaborative environments with 5 dimensions to record the purpose and forms of learner dialogue. While these dimensions are able to provide more detail of the purpose of interactions than those we have used previously, we chose to remain with our more general content analysis as a means to explore the general nature of student interactions in the planned environment. Our intention in this initial study was to determine the capacity of the chosen interventions to promote dialogue and discourse through collaborative learning. Our investigation sought to establish the forms of dialogue that resulted to determine if students' levels of cognitive activity and engagement were influenced. The dimensions used in this study are explained in [Tab. 1].

Type of Interaction	Description	Example
social	students discussing elements of a social nature and not directly associated with the lesson	S1: What course are you studying? S2: Multimedia and communications. S1: Does that mean you know my friend John?
procedural	students discussing matters relating to procedures and steps associated with the learning materials and WWW browser	S1: What do we need to do here? S2: I think we should go to the first screen and read the instructions. S1: Okay, I think you click here to do that.
expository	exchanges where facts and knowledge are passed with little further elaboration or development through discussion, articulation of information	S1: The screen design here is quite good. S2: I like the colour and the images. S1: The text is well laid out and easy to read. S2: The format is a bit wide.
cognitive	students' discussion leads to knowledge development and involve exchanges which demonstrate critical thinking and reflection	S1: Is this Home Page better than the previous ? S2: It's much clearer and more spacious. S1: I think the space makes the page less cluttered and the picture is less busy. S2: The space also make the links more apparent.

Table 1: A framework for describing interactions in collaborative learning environments

Outcomes

Group 1: Chris and Kate

This pair of students comprised both an experienced and inexperienced WWW user. The pair used the printed guide which provided instructions and directions in how the WWW document should be used. Initially a large number of procedural interactions were observed as the pair decided the format and scope of the task they had been set and explored the WWW environment. The more experienced user, Chris, assumed control of the mouse and maintained this for the whole of the session. Kate had had some experience with the WWW and appeared quite comfortable with the navigation and linking processes employed by her partner.

As the pair settled into the exercise, they adopted a style of displaying the screen information and each reading it quietly to themselves. This left many periods in the observation where no discussion or exchange was taking place. While other students often used such opportunities to discuss and articulate the information, this pair displayed a tendency to work independently and maintained this throughout the session. Chris would wait until Kate had appeared to have finished reading before moving to link to other pages and sites. There was rarely any discussion about which site would be chosen. Kate appeared content to let Chris choose. When pages appeared, Chris would often make a comment, for example, " nice graphics" and "I wonder what this means?". Mostly Kate would say nothing and Chris would choose another site and browse again. There were many examples of expository interactions evident in these stages that involved very short and abrupt information exchanges.

The printed guide contained a copy of the activities from the WWW document and provided space for written responses. It was intended that the students would read the textual information in each WWW chapter and attempt the activity once they had developed some understanding of the current chapter. This pair of students tended to commence the activity as soon as they moved to each new chapter. Once again, this was done independently and there were several minutes of silence as the pair made their own notes. On several occasions, Chris commented aloud as he wrote things down and Kate concurred, but the discussion rarely developed further. This limited form of collaboration gave rise to a large number of very short expository interactions, the majority of which were initiated by Chris. In many instances Kate's contribution was agreement with no further elaboration. This form of communication limited the scope for cognitive interactions.

The last chapter in the document provided links to Home Pages of movie companies and when these sites appeared, the conversation became more discursive. Both students were interested in movies and immediately began discussing aspects of the movies that were displayed on the screen. These interactions were clearly social in nature and bore little relevance to the design aspects which were meant to be leading the conversation. [Tab. 2] shows the number of the different types of interactions observed between these students. The table shows a relatively small number of interactions in the 80 minute session and the absence of any cognitive interactions.

Type of interaction	Frequency	Relative Times
social	5	10%
procedural	15	38%
expository	31	52%
cognitive	0	0

Table 2: Interactions observed between Kate and Chris

The lack of cognitive interactions among these students was unexpected. While there appeared to be many opportunities in the learning materials for the students to reflect on issues and to discuss ideas and findings, they did none of this. The pair were clearly mismatched for this type of learning activity. At the same time, it appeared that the form of the printed guide also acted as an impediment to the collaborative activity. In following the guide, both students made their own meaning of the content that was presented and created independent accounts in their notes. The guide did not specifically encourage students to work collaboratively and in this instance, they chose not to. In providing a focus for student learning, the guide encouraged the students to follow the lesson content in a structured sequence and this limited the level of cooperation and collaboration that was observed. It is likely that had the guide carried less explicit instructions, higher levels of collaboration may have occurred.

Group 2: Raelene and Alan

This group also comprised a novice and experienced WWW user. This pair worked without the printed guide and followed their own path through the WWW pages. In the first stages of the session, there were a number of procedural interactions caused by Alan explaining different features of the browser and the pages they were downloading. Raelene was content to let her partner take the lead in deciding which links to take and when to proceed. There was a number of expository interactions as Raelene inquired further from Alan about the sites they were visiting and the content of the pages displayed. The lack of direction, from the printed guide, for example, encouraged collaborative interactions by virtue of the need for the students to agree on a learning strategy. This pair spent considerable time on the first two chapters but there was little evidence of any purpose or focus in their activity. Alan concentrated on the textual components of the chapters and followed the links that were provided going from one to the next with no apparent aim in mind. During this browsing, there were many expository interactions and few cognitive interactions. The pair viewed the pages that appeared and commented to each other on different aspects of the pages.

The pair attempted none of the activities but spent considerable time working through the quiz questions. The use of a printed guide may have ensured that the activities were attempted and could have led to the students' attention to more meaningful information and content. It was in reading and answering the quiz questions that most of the cognitive interactions occurred. The pair discussed the solutions to the questions and often built on each other's responses. The open-ended nature of many of the questions encouraged this reflection and critical thinking and the contributions of each partner often led to creative and joint solutions being developed. The nature of the discussion and exchanges between these two students tended to change as the lesson progressed. There were many interactions of a procedural nature at the start as Alan explained features to Raelene. The level of procedural interactions may have been different had Raelene had more WWW experience.

Type of interaction	Frequency	Relative Time
social	2	2%
procedural	32	32%
expository	28	41%
cognitive	13	25%

Table 3: Interactions observed between Alan and Raelene

[Tab. 3] shows the relative numbers of interactions observed among these students and the relative proportion of time of each. Both the design of the learning materials and the nature of the learning environment had led us to expect that there would have been a higher level of cognitive interactions than which actually occurred. Factors which appeared to limit the number of such interactions in this instance included the pairing of a novice and experienced user, the high level of browsing, students' choice not to undertake the activities and the failure of the students to establish an appropriate pace to cover the contents of the WWW document in the given time.

Group 3 Danni and Vicki

The third pair of students were friends. This pair also did not have the printed guide and were free to use the materials in their own way. Observation of their behaviours clearly indicated the value of cooperating partners. The pair chatted freely throughout the lesson and shared the *driving* equally. The high levels of cooperation saw a large number of short procedural interactions interspersed throughout the session as each indicated the next step that might be taken and waited for any dissenting or alternative suggestion. In most instances, a statement of the form, "let's go here" and a pointing action to a link on the screen led to that action being taken. Often the student without the mouse made the suggestion as to the next site to visit or link to make, and the other effected the action. In this group, the student with the mouse did not lead but rather acted as the agent who carried out the next step according to her own or the other partner's wishes. The mouse was swapped frequently. Both students interacted freely and large numbers of exchanges were recorded [Tab. 4]. While there were many procedural interactions, the brevity of the exchanges reduced the relative time of these. At the same time, there were few cognitive interactions overall but the level of discussion involved for each saw an appreciable amount of time in the session spent in this form of interaction.

Type of interaction	Frequency	Relative Times
social	1	1%
procedural	34	23%
expository	45	60%
cognitive	6	16%

Table 4: Interactions observed between Danni and Vicki

This pair followed the WWW document sequentially and attended to each component in turn. As the students worked through each activity, there was a large amount of discussion and articulation of the content that was being presented and a considerable amount of important information was discovered and gleaned by the students in this way. The textual information contained in the body of each WWW chapter served to reinforce the students' learning but the links in the body of the chapters appeared to be distracting. We found ourselves wondering about the value of these links. They encouraged browsing and unstructured investigation while those in the activities formed part of a planned inquiry. There were a few occasions during the session when the interactions were cognitive in nature.

Summary and Conclusion

Observations of student behaviours did not provide confirmation of our contention that the planned environments would encourage cooperation, reflection and articulation among students. The use of the collaborative setting was expected to yield a far higher amount of cognitive interaction between the learners. There were a number unexpected outcomes relating to the influence of the printed guide and the investigative activities on the extent and forms of the interactions observed. In all groups, there were considerably more procedural interactions than anticipated. In some cases, this was brought about by student uncertainty in the unfamiliar environment, elsewhere it was brought about by students establishing working patterns. It was clear to us after observing the students that any new learning environment would likely reflect this outcome. We would expect if these students attempted other WWW activities now, there would likely be less of these interactions. However the procedural interactions associated with cooperating behaviour would still remain.

Expository interactions often involve articulation and tend to reflect lower levels of cognitive engagement but they help to build understanding by the passage of information and content between learners. In ideal circumstances, expository interactions can and should initiate cognitive interactions. There were many instances in this study where students exchanged ideas and views that could have led to higher-order thinking and exchanges but didn't. Often this was as a result of one student failing to attend to what the other was saying and not extending the item under discussion. Even the most cooperative students tended at times not to listen to what their partners were saying. One factor contributing to this appeared to be the lack of learning goals. The activities did not require students to derive any particular or agreed outcome. Also, the large amounts of textual information and links appeared to distract students, encouraging browsing and unstructured inquiry.

We felt that the principal reasons why there were fewer cognitive interactions than expected and why the number and forms of interactions varied within the different groups were attributable mainly to: group composition, inappropriate composition of groups can lead to non-collaborative environments; lack of instructional support, in instances where students are not guided by instructional support, they can choose to follow paths of their own choosing and avoid activities which the instructor may wish them to complete; inappropriate information display, it does not appear appropriate to use large amounts of text and investigative activities in WWW pages; inappropriate design for collaborative learning activities, in collaborative settings, activities need to be designed specifically with collaborative components and suggested roles for group members that encourage discussion and articulation; lack of learning goals, the students were not guided by any particular goals or stated outcomes; and distracting elements, the inclusion of links and examples in textual and content related sections of WWW materials can distract some learners from the information being presented;

To gain maximum advantage from the collaborative and investigative environment, we suspect that more ideal forms of implementation are those where: group composition is more carefully planned; where students are required to provide feedback of some form on their outcomes as an inducement to maintain focus and complete activities; and where this form of learning exercise is introduced after students have become more familiar with the WWW; and where more adaptive forms of scaffolding providing selective assistance are employed, for example, through an instructor or context sensitive help in the programmed materials. We intend now to revise our instructional materials to accommodate the changes suggested above and to repeat the study. We will look to see whether the changes are associated with increased levels of student collaboration, reflection and articulation and increased levels of cognitive interactions.

Edith Cowan University,
Western Australia.
m.lake@cowan.edu.au

Abstract: This paper describes a project in Western Australia in which teacher-education students needing to learn practical skills of, and a theoretical understanding about, audiographics as an instructional technology, did so in a course where the technology itself was used as the delivery medium. This method of course delivery was characterised by a teaching program which involved such instructional attributes as: knowledge construction; authentic contexts; student-centred learning and collaboration. An evaluation of the course demonstrated high levels of student performance and satisfaction and positive learning outcomes.

Introduction

Many times in university courses, students are required to develop a defined set of skills and knowledge for application at some later stage in their careers and vocations. Teachers, for example, are often given formal courses in computers and technology to enable them to apply these technologies in their future teaching. These courses often take the form of lectures, demonstrations and practical classes. Research clearly shows that a person's ability to apply skills and knowledge is very much dependent on the way they learned them. Formal courses of instruction in teacher education as described above have frequently been found to limit understanding and future application especially in instances where technology and technological applications are concerned [see Robinson 1993]; [Downes 1993].

Consider our dilemma in teaching a pre-service teacher education course, Rural Education, at Edith Cowan University in Western Australia. This course aims to prepare students for, teaching in rural schools and teaching at a distance. Young teachers in rural schools are exposed to a range of difficult situations not encountered by their city counterparts. The geographical and social isolation resulting from being posted to a remote rural setting creates many difficulties as they strive to establish their competence and confidence in teaching. They are professionally isolated from the wide range of expertise and experience to which they have been accustomed and have restricted access to guidance and support systems. For these students to be successful in their rural schools they also need to have learned and developed self-sufficiency in the use and application of instructional technologies, confidence and ability to sustain technology skills through self-teaching, and skills in locating and accessing appropriate information and resources for rural teaching.

Audiographics Technologies

A standard instructional technology used for delivering educational programs within rural schools in Western Australia is audiographics. Audiographics describes a process where teachers and students at remote sites are linked through two main channels: an audioconferencing channel providing real-time oral communication and a computer channel providing a shared and interactive computer display. Audiographics is a powerful instructional medium for rural schools. Its application in WA has increased curriculum offerings to rural students with such instructional advantages as attitudinal and motivational gains and cognitive improvements [Oliver & Reeves 1994]; [McLoughlin & Oliver 1995]; [Oliver & Reeves 1996].

Since learning to teach with audiographics was already a component of the course, we designed an instructional approach that made use of the audiographics technology as a delivery system. This technology provided us with a demonstrated and strong instructional support for our teaching and also an environment where we could develop students' skills with telecommunications technologies. Applying the technology in this fashion seemed to provide a learning environment that would be meaningful and effective [e.g. Diem 1989]; [Novak & Knowles 1991]. Through the integrated nature of the instruction, it was anticipated that students would develop transferable and generalisable skills and knowledge that would be applicable in future settings [e.g. Prawat 1992]; [Rovegno 1993]. At the same time, by designing an on-campus course that used the best attributes of distance education, we hoped to also provide a setting to develop students' skills and abilities as independent learners and strong supporters of distance education as an instructional process.

The Program Design

The fundamental factor behind the design of the new course was the premise that learning environments that support knowledge construction and contextual learning are more effective and more successful than those that support knowledge transmission alone [Reeves 1993]. Learners receive knowledge from environmental stimuli and learning depends on how that knowledge is used. Information is coded and learned according to the meaning ascribed by the learner [Piaget 1954]. It was our intention that by providing an environment in which students learned through the medium of audiographics, they would construct a meaningful and relevant knowledge base of this technology and its use as an instructional tool. We wished the students to become active learners who would process lesson content through experiential and meaningful learning activities.

Another aim of the project was to create a student-centred learning environment that facilitated high levels of learner control. In rural settings, both students and teachers are often required to assume control and take responsibility of their own learning programs. In settings where the teacher assumes a facilitative and coaching role, students become active in the learning process. Rather than attending to a teacher-student dialogue, students can be working in a more autonomous role either individually or among themselves. Our project had two reasons for giving students much more control and personal autonomy in their learning. In the first instance they would likely benefit from this in terms of knowledge development. In the second instance, it would enable them to experience first-hand the forms of learning environments often experienced by distant students, giving these new teachers a realistic set of expectations and impressions of such instructional settings.

Perhaps the aspect of our project with the strongest potential for enhanced learning outcomes was its practical and authentic context. There is significant support in the literature for the benefits of contextual learning where students are taught and learn in environments that closely match reality. A major criticism of much of our current dominant pedagogical schemes is that they are too abstract, removed as they are from 'real world' experience [Brown Collins & Duguid 1989]. If knowledge, skills, and attitudes are learned in a context of use, they are more able to be applied and used in that and similar contexts.

Student behaviours that often have a significant impact on performance and learning are those brought about through collaborative and cooperative activities with peers [e.g. Slavin 1995]; [Herrington & Oliver 1996]. We sensed that there were strong benefits to be derived from our course if we encouraged peer collaboration. Apart from the increased understanding brought about through talk, the collaboration could provide support and coaching for the students in the absence of ready access to help from the instructor. Socio-learning theories such as situated learning highlight the place of coaching and scaffolding as integral components of effective learning environments [Collins Brown & Newman 1989]. In our course where instructor support was to be limited, the need for peer-support was seen as a critical element. At the same time, by experiencing first-hand the benefits of collaborative learning, the students would be likely to apply this strategy in their own teaching.

The Audiographics Course

With these ideas and principles in mind, a curriculum was developed for audiographics delivery in the form of modules with supporting materials. The curriculum was planned to be implemented in a virtual classroom with small groups of students in various locations across the university campuses linked through audiographics technologies. The audiographics links were designed across a series of lessons to provide instruction in appropriate parts of the course and to guide and direct students in their independent use of the supporting learning materials. It was planned that students would receive instruction and direction through attendance in audiographics sessions and would then independently and collaboratively complete a series of prescribed tasks and activities.

The content of the course required students to learn how to operate and apply: the hardware associated with telecommunications and audiographics; the mechanisms and processes by which the telecommunications and audiographics technologies operate, the skills required to independently use computers; telecommunications, audiographics and appropriate software; and the instructional skills and relevant pedagogy associated with teaching and learning with audiographics and telecommunications in rural schools.

Because this course was to be delivered in an external form, a range of learning materials was developed to form the basis of the independent student activity. The materials that were prepared and compiled included: a course guide, a booklet detailing the course, the time frame, the modules and instructional episodes and the activities and tasks to be completed; a set of readings describing the technology, its application and implementations; video materials showing examples of actual audiographics teaching and learning; instruction manuals and guides for the audiographics equipment and resources; a CD-ROM with materials to assist audiographics lesson planning; instruction manuals and activities for the Macintosh computer system; instructional materials describing the use of the audiographics software, Electronic Classroom [Crago 1992]; and an electronic document on the World Wide Web describing distance and rural education technologies and their applications.

This course was delivered to the 13 students enrolled in the unit ED 3282. Audiographics is best suited to small groups of students at separate sites and 13 students was an ideal class size for this project. The course comprised five 45 minute sessions with an audiographics link and eight one hour sessions where students worked independently. The audiographics lessons were delivered by the first author from a remote campus while the second author acted in a support capacity to the students on the remote campus. The program ran across a six week period during which time the students were required to complete a range of tasks leading to the final sessions where students worked in pairs to plan and deliver an audiographics lesson to their peers. Throughout the course, communication with the distant lecturer was limited to the audiographics technology and telephone, a restriction that raised students' awareness of the conditions of learning through such technologies.

In each audiographics lesson, four students in the class sat at the computer and interacted with the distant teacher. The remainder of the class sat behind, following the lesson and reflecting on the teaching and learning strategies being employed and the responses of the students. At the end of each lesson, the group assembled for 15 minutes to discuss the teaching that had taken place and to consider various aspects of the learning environment unique to this form of teaching and delivery. By the end of the course, most students had been active participants in two, and observers of three, audiographics lessons.

In the process of conducting the course, we established a series of research questions that we sought to investigate as a means of evaluating the innovations we were using and as a means to improve the course for subsequent implementations. The particular areas of inquiry addressed by this research were: students' responses to the alternative instructional format; the relative effectiveness of the different components of the program; and the extent and scope of the learning;

Throughout the course, a number of data collection methods were employed. Students were asked to complete questionnaires at various stages and records were kept of their work across all activities. Interviews were conducted among the students and the lessons delivered by students in the final sessions were recorded.

Results

1. Students' responses to the alternative instructional format

When at the end of the course the students were asked to indicate the main ways in which this course differed from others, by far the most common responses were the high levels of practical work involved and the use of the computer technology. Perhaps the views of the students were well summed by one who said:

> "In other courses, we would have read or been told how the technology works, in this course, we were shown and we experienced it."

When asked to suggest the ways in which this course was superior to others, the more common responses were, that in comparison to others, this course:

- was more practical;
- used technology as a fundamental component;
- catered better for the needs of individual students;
- was very motivating and stimulating;
- encouraged and supported higher levels of student participation; and
- compelled students to keep up and to learn what was going on.

We also asked students to inform us of ways in which the course carried disadvantages or was less effective than others. The main responses were of the form:

- using technology hinders learning when technical problems arise;
- not being able to see the teacher is a disadvantage;
- not being able to form a relationship with the teacher was a problem; and
- it takes longer to learn by doing than by lecture mode.

One interesting response from a student was the comment that:

> "I'm not sure that audiographics is as good as people claim. I personally learned very little from the audiographics sessions. Everything I learned in the course, I had to teach myself."

We took this comment to be more positive than negative. It demonstrated to us that the student recognised that he was very much responsible for his own learning and had learned through his own activities. At the same time it demonstrated that there may be students who feel that they learn by *being taught* and when this aspect is removed from the classroom and the onus placed on the student to learn, there may be some who will not appreciate the different teaching style despite its effectiveness and learning potential.

2. The relative effectiveness of the different components

To gain students' perceptions on the component of the course through which most was learned, at he end of the course each was asked to rank the different media/instructional components. The results of this ranking are shown in [Tab. 1]. The sum of the rankings provides an index, the smaller the number indicating a perception of a higher effectiveness and contribution to learning.

The students' results clearly indicate that they considered the practical components to have contributed the most to their learning. The three components with the lowest indices were: the audiographics lessons themselves; the lesson planning tasks; and the actual lesson delivery. The two components that were considered to contribute least were the WWW reading activity and the video, both of which were rich in information but presented in very passive modes.

student number	1	2	3	4	5	6	7	8	9	10	11	12	13	Total
audiographics	1	2	1	4	2	5	5	1	2	3	1	1	1	**29**
readings	3	1	2	1	6	7	7	5	1	5	3	4	5	**50**
World Wide Web	7	7	7	7	7	7	7	7	7	7	6	7	7	**90**
video programs	6	5	6	6	5	6	6	6	6	6	7	5	6	**76**
computer lab.	4	6	5	5	3	2	2	4	5	4	2	6	4	**52**
lesson planning	5	4	4	3	1	4	4	2	4	1	4	2	3	**42**
lesson delivery	2	3	3	2	4	3	3	3	3	2	5	3	2	**38**

Table. 1:
Rankings showing the students' perceptions of the components of the course which contributed most to their learning

The contribution of the audiographics lesson presentation to learning was evident in ways other than student judgments. For example, at the end of the first lesson before any theoretical discussion was held on effective pedagogies for audiographics teaching, students were asked to comment on what they considered would be important instructional considerations for teaching. Students commented on the need for:

- lessons which could capture and maintain interest;

- higher levels of student activity than conventional classrooms;
- strong management routines;
- instructions and directions to be given clearly and succinctly; and
- smaller rather than larger groups in the remote classrooms.

It was clear from students' responses that through practical participation in audiographics sessions, much of the description from the textbooks was already known by them. It was perhaps this reason that caused the WWW document and video programs to be considered the least effective components in the course: most of the information carried through these media had already been gathered by students through experience and there was little more that could be learned from these other sources.

3. The extent and scope of the learning

The measure that we chose to use to assess the scope and extent of learning in this project was students' performance in planning and delivering an audiographics session at the end of the course. The use of this activity provided an assessment that truly reflected the intended learning outcomes.

The criteria by which students were assessed in this exercise were:
- the planned lesson, including the nature of the learning activities planned, the instructional screens created, the planned learning sequences, the supporting materials developed; and
- the lesson delivery; the quality of the interactions, the nature of the instructor-student communications, management strategies employed.

We observed six lessons presented by students in team-teaching modes. In all instances the lessons were well prepared and reflected a good knowledge of the forms of teaching activity required to successfully learning at a distance with this technology. The real measure of the success project was in the lesson delivery. All six groups delivered lessons that although varying in amounts and levels demonstrated the following characteristics:
- sound management strategies;
- engaging instructional sequences;
- low levels of teacher-talk;
- student collaborative and cooperative activities;
- motivating and stimulating presentation modes; and
- computer as well as oral interactivity.

Perhaps the most telling indicator of the scope and extent of the learning came from students' responses at the end of the course. While many had been anxious and concerned participants on day one, by the end of the course, most students indicated that they recognised that although they didn't know all that was needed for total independence at this stage, they felt comfortable enough to want to become involved in this form of teaching in their initial appointments. They felt confident that they had the skills and knowledge to at least make a start and learn what ever was needed from there. Even those students with least computing skills demonstrated this form of confidence. We were heartened to see that most students had developed a confidence towards self-sufficiency and had expressed the view that in the future, they could learn through their own resources.

Summary and Conclusions

This paper has described a project in which students learned practical skills of, and a theoretical understanding about, a distance education technology in a course where the distance education technology itself was used as the delivery medium. This method of on-campus course delivery was characterised by a teaching program which involved such instructional attributes as: knowledge construction; authentic contexts; student-centred learning and collaboration. An evaluation of the course demonstrated high levels of student performance and satisfaction with the course and provided feedback which indicated that the project was very successful in most regards.

The evaluation revealed that students were very positive about the alternative instructional format used with most seeing it as superior to conventional instruction. There was evidence that all the characteristic attributes had a positive impact on student learning and there were a number of learning outcomes that most likely could not have been achieved through conventional teaching means. The instruction led to the development of the necessary skills and knowledge needed to develop effective teaching programs with this technology and it was evident that much of the learning came from students activities and experiences rather than from content gained from the course materials. The components of the course which the students saw as most effective were those related directly to practical teaching with the technology. Our secondary aim of developing students ability for self-instruction also appeared to have been met with most students demonstrating high levels of competence and confidence in independent and self-regulated learning activities.

Buoyed by the success of the project, we plan to implement the course again drawing on the more successful components and adding new features to extend the scope and learning potential. We are planning to include students from similar courses in other Australian universities in the next course. To cater for the changed nature of the learning environment that this will bring, we plan to encourage and enable communication and collaboration between the remote learners through such associated technologies as e-mail and listservs as described by [Yakimovicz and Murphy 1995]. Each of the new features will enable students to extend their knowledge of effective teaching strategies and technologies complementing teaching and learning at a distance and provide new tools for personal development.

Introduction

There are a variety of technological means for supporting synchronous collaboration. It is clear that the number of individuals simultaneously using such systems and whether or not they are co-located alters in fundamental ways the patterns of interaction. If such systems are to be used in education one question of key importance is, are there pedagogical thresholds on scale of simultaneous use for particular learning environments which build on such technologies? Over the last ten years the authors have designed and evaluated a number of object-oriented environments that support the learning of concepts in science. We are committed to an object-oriented approach for various reasons, the most important being the ease with which direct manipulation interfaces can be supported. For this paper we briefly summarise a re-evaluation of that work from the perspective of constructing a taxonomy of learning behaviours observed in different technology mediated collaborative settings. The paper will conclude by describing the results from a new study currently in progress to systematically evaluate Kansas, a new very general and powerful environment that supports synchronous distributed collaborative learning.

Context

In recent years a number of researchers have investigated what happens when students work collaboratively, especially in the domain of science problems. In many circumstances students working together on a problem benefit more than those working alone. But how do these benefits arise? Some workers attribute learning gains to the increased cognitive resources available for solving the problem (two heads are better than one), some to increased verbalisation while working, some to the beneficial effects of externalising conflict and some to the co-construction of knowledge. Thus, there is still a difference of opinion as to exactly how working with one or more partners enhances learning, and, in particular, what makes an effective setting for collaborative learning. As benefits also appear to be dependent on a number of task specific factors, research on these raises a number of questions about how to best design collaborative learning experiences. The two key dimensions of variation this paper is concerned with are the number of learners working together and whether or not they are physically co-located. We are particularly interested in the ways in which the benefits of collaboration can be harnessed for collections of students learning science at a distance from each other. In our past work we have examined the benefits for science students of working with simulations, and exploring the potential for students of simulations to solve problems of various types. The technological basis of this is our past work on the Alternate Reality Kit (ARK), SharedARK and DM3 (the Direct Manipulation of Mechanical Microworlds) . With ARK we worked with co-located pairs, with SharedARK we have worked with physically separated pairs and with DM3 we studied co-located triads of learners.

ARK - Alternate Reality Kit

ARK (Smith, 1990) is a system for creating interactive animated simulations implemented in the Smalltalk-80 programming environment which includes some unique features chosen to make its simulations both powerful and unique. The interface is faithful to a physical world metaphor - all objects have a screen image, a velocity and can experience forces. Even the laws of physics can be treated as objects and therefore manipulated and changed. Our experiments with instructional physics simulations (for example teaching the conservation laws) implemented in ARK (Smith, O'Shea and Scanlon, 1987) convinced us of the value of interfaces based on physical metaphors and demonstrated that the ability to perform experiments where students could see the effect of the laws of physics being otherwise had enormous educational potential, and that the design of suitable tasks played a large role in the success of the simulations. In our work with ARK we noted that its richness and complexity was such that a classroom of users observing a single workstation 'driven' by one of them could become distracted and demotivated. On the other hand lone users did not perform as successfully as pairs of users exploring simulations that were sometimes designed to replicate real world phenomena and sometimes designed to illuminate the laws of physics by breaking them. There was also interesting variation in the styles of task division adopted by the pairs which ranged from very even turn-taking to distinct roles of driver and navigator.

SharedARK

The design of SharedARK, a distributed version of ARK, allowed us to experiment with pairs of users working together while communicating from remote locations with an audio and video link. This sort of technology is vitally important for distance education institutions. A system for remote collaboration developed by Smith (1992) allowed two users in separate rooms each with a workstation to run a shared physics simulation. A number of pairs of graduate students were linked via various forms of communications devices. Some had only an audio link, whilst others had the audio plus a camera monitor device called a video tunnel which enabled eye contact. These conditions were compared with situations where participants worked together in a room, either side-by-side at the interface, or on opposite sides of a communal desk. We observed distinct effects on the problem solving performance of the students (see Scanlon et al., 1993) revealed by video protocols analysed and utterances related to eye contact and simulation events categorised in a variety of ways using a methodology described in Taylor et al. (1991). One finding from this experiment was the important role of eye contact through the video tunnel in establishing successful collaboration, and in particular during the high-level planning stages of the interaction. Another finding was that the distributed technology increased the social distance between the pairs of users and that this prompted the users to be more articulate about their problem-solving strategies and more careful about how they used talk in guiding collaboration. This experiment showed that such distributed technology was usable but mediated collaborative problem-solving behaviours that were different in kind from those observed when the same simulations were used by physically co-present pairs.

DM^3 - Direct Manipulation of Mechanical Microworlds

"The Conceptual Change In Science (CCIS) project" (O'Shea et al 1993) aimed to improve the science understanding of a mixed group of thirty thirteen year olds using specially designed computer software. The concepts to be studied were those from Newtonian mechanics. The software consisted of scenarios implemented in DM^3 (the Direct Manipulation of Mechanical Microworlds) computer program written in Smalltalk-80, strongly influenced by the design of ARK. These scenarios were brought to life in simulations which children could use both in structured experiments and in an informal way. The scenarios combined with support materials (e.g. worksheets) to form an integrated teaching package which also included 'real' practical experiments. The scenarios were constructed to provide opportunities for pupils to construct a Newtonian set of rules for force and motion in a supported software environment, through observation of patterns of events and data on the screen. Time was equally divided between 'real' and computer practicals. Children worked in affinity groups. Each scenario is designed to address particular misconceptions. and the pupils need to collect empirical data about prototypical motions, and to identify relationships between variables. Computer experiments based on the scenarios combine with support materials such as worksheets and real practical experiments combine to form an integrated teaching package. The practical work requires pupils to make predictions about the outcomes of either type of experiment, giving the reasons behind their predictions and then check the outcome. In the CCIS studies we noted that it was not possible to support the formation of mixed gender affinity groups but the single gender triads were very productive and characterised by very clear role division rather than turn-taking amongst the individuals and the emergence of a new co-ordination role which we had not observed in our earlier studies with pairs.

Kansas

This is a distributed classroom which allows several physically distributed users to move about in a 2D space (called "Kansas" because it is very extensive and flat). Moving together and apart in Kansas will make and break audio connections among users so a group can easily divide into subgroups for independent discussions. Users each have a window in which they can see their local portion of Kansas. This window may contain objects relevant to the subject matter. Each user sees a small local rectangular portion of Kansas. Users can scroll their viewpoints across the vast surface, causing their rectangles to overlap in order to collaborate, or can move away from others to work alone. Kansas users can be anywhere in the physical world. Kansas supports interactive animation. Kansas is written in itself - it is integrated with the Self programming environment, so anything can be modified arbitrarily while the system is running. The Kansas shared space is written in the Self language. Our previous experiments with SharedARK suggest the importance of eye contact in establishing successful joint working, but recent work by Whitelock et al. (1995) suggests that audio communication might be sufficient for students working on a shared simulation to establish adequate role and task division.

Scaleability Experiment

At the Open University we now have a version of Kansas which supports upto 5 simultaneously active users (or, of course, up to 5 groups of users) and they can be given access to audio or both video and audio links between each of the 5 locations. We are therefore asking what the effects of increasing scale from 2 or 3 active users on the types of behaviours and roles we observed in our earlier studies. We have developed a benchmark group statistical problem-solving task which is simple to state, understand and support in Kansas but which, like many of our standard tasks used in past studies, has a simple solution which is counterintuitive. By constraining ourselves to such a task and by using an environment which has a similar interface to that used in our previous studies we are able to focus carefully on scaleability and contextualise the results we get from this study with our past ten years work in this area. The experimental task involves deciding what advice to give a contestant who is the game show situation where, having chosen one of three doors which might lead to the grand prize, the contestant is shown behind another door which does not reveal a prize and is then asked if they wish to change their choice to the third door. The groups of subjects explore the problem with the aid of a shared simulated game show setting, a shared note-taking tool and a remote human host who communicates via audio or video link. The subjects display many standard misconceptions associated with probabilistic reasoning. Many are convinced the random means fifty per cent of the time. They display superstitious behaviour with respect to patterns and in one case became convinced that one of their group was 'lucky'. Non-mathematical notions of fairness are also invoked, such as that it must now be the middle doors 'turn'. Subjects also often make explicit the idea that changing door choice entails the higher 'emotional risk' of leaving a choice that turns out with hindsight to have been right.

Preliminary Results

The preliminary results of our studies can be related quite nicely to our past experiments with SharedARK and in the CCIS project. The difference between the audio only situation and video link situation is preserved in the Kansas context. In the CCIS experiments we found that three students working together could divide tasks of these types between themselves in a rational and effective way. This also holds in the current round of Kansas experiments and for educational purposes we are becoming more and more convinced that three students working together gain more incidental learning benefit than two or four. One tidy three way division that was adopted was one person choosing the door, one person operating the simulation and the third person taking notes. We noticed that moving from groups of three to groups of four appears to add dramatically to the extra negotiation about how to organise the task. Our experience with a groups larger than three is that the overhead of, for example, deciding which part of the task to do next can grow out of all proportion to the actual problem solving necessary to make progress. One ameliorating tactic that we have noticed groups larger than two learn to adopt is to indicate preferences and choices by the location or movement of their mouse cursors on the shared screen. We are interested to discover whether other economical non-verbal methods of joint problem solving are evolved by groups of learners or problem solvers using systems like Kansas. The main result of our research is that learners behave differently when they use systems like Kansas from the way they behave when they are in the same room and that the dynamics of groups of learners alters in very distinct and measurable ways depending on the number of subjects who are simultaneously working together. A key aspect of shared system use that affects behaviour is the clarity and economy of the note taking methods devised or adopted by the group. Some groups generated chronological and detailed records of every use they made of the simulation. The level of detail was such that they had to scroll in a shared window to view the data and they often "could not see the wood for the trees". In these situations groups often agreed on counterfactual summaries of the data that matched their expectations or prejudices, such as its "fifty fifty' either way. Larger groups were more likely to record unmanageable amounts of data and to agree incorrect summaries. On the other hand, when groups devised simple highly focused ways of summarising the data that could be viewed in a single window they were much more likely to identify and resolve mathematical misconceptions. The most elegant summary was a two by two matrix of success/fail versus stick/change where the appropriate cell was updated by one of the subjects after each go at the game. One group also used the share note-taking tool to explore illuminating hypothetical cases such as the 100 door case. So one important gloss on our early results is that not only do groups of size smaller that four problem-solve together more effectively using the technology, they also devise more effective shared tools to support their learning and exploration.

Concluding Comment

We believe that object-oriented environments that support synchronous distributed collaboration will play an important role in the support of distance learning. We conjecture that it will be possible to demonstrate that much larger numbers of simultaneously active learners, distributed as individuals and small groups will be able to productively learn together. At the same time, there are simple a priori arguments that say there has to be threshold limits to the number of individuals and groups who can usefully be coactive. Smith's successfully implementation of Kansas now makes it possible to test our scaling up of collaborative group size conjecture and to explore the scaleability limits of this new technological support for synchronously working collections of distant learners..

Abstract: PACER (Personally Active Computing Exploration Resource) is an online learning resource that enhances the viability and efficacy of education through interactive learning. PACER provides a self paced, interactive learning system by which students learn complex and abstract concepts which frequently defy traditional classroom teaching methodologies. Development of this national model is accomplished through an object-oriented design, implemented with the JAVA programming tool and delivered across multiple computer platforms through the World Wide Web. In this paper we present the design and implementation issues of PACER system together with some examples of interactive learning.

Introduction

PACER is an interactive learning environment designed to engage students in learning. The goal of the project is to develop an educational system which takes advantage of emerging technologies to provide interactive, demand-driven simulations which enhance comprehension of abstract concepts in computer science. The PACER system includes three fundamental objectives: simulation and experimentation, connection to supplementary information and delivery to a wide audience across multiple computer platforms. All three objectives are required to support the educational demands of students who struggle with difficult theoretical material, seek access to information round-the-clock from home and work and use a variety of computer platforms. Interactive environments such as PACER are an effective, readily accessible means to support active student learning.

The term interaction has a significant meaning in our definition. Even though every World Wide Web-based learning environment can be considered interactive, they are actually passive learning environments. For example, World Wide Web learning material on modern art allows one to browse through several pages of art by popular artists. It will not allow one to manipulate the artwork in anyway. The essence of science and engineering is active learning through manipulation and observation. In the PACER system, students can interactively manipulate the objects (models), observe the changes, and improve their level of comprehension of abstract concepts.

Implementation Strategy

Programming Language Selection

PACER is a learning tool designed to capitalize on the benefits of a distributed system. The design standards include (1) internetworking/World Wide Web support, (2) complex graphics (3) interactive capabilities (4) object orientation, and (5) user friendly programming. It was critical to implement a system which offered platform-independence while being sophisticated enough to adequately support graphics and user interaction.

Several platforms including TCL and TK [Ousterhout 1994] were considered. However Java [Cornell & Horstman 1996] which is a recently released, object-oriented and independent programming language from Sun Microsystems, appeared to be particularly appropriate for design implementation.

The language of Java [Geary & McClellan 1996] is well suited to inter-networked distribution because of its hybrid compiled-interpreted nature. Java source programs are compiled into a format called bytecodes. Java bytecodes, programs, also called classes, are designed to "run" on a hypothetical computer called the Java Virtual Machine (JVM). Thus, a single set of source code and single compilation is supported on any platform type running a JVM. Platform independence was particularly important for the PACER project. Effort is focused on program development and enhancement, rather than porting to several hardware and software platforms. Java's ability to provide platform-independence is also beneficial to students. Without this capability, users would be denied access to the PACER simulations due to a mere lack of access to "supported" hardware or software platforms. Java programs can be readily distributed via the World Wide Web by embedding the programs (called applets) into standard hypertext documents through the use of special HTML tags. Because today's popular browsers, versions greater than Netscape 3.0 and Internet Explorer 3.0, support Java applets, PACER can be effectively distributed to users. Critical to implementation was Java's ability to support graphical demonstrations of abstract concepts as well as support user input interfaces. Review of Java's performance in numerous applet development concluded that all graphic and user interaction design standards were satisfied.

Although Java provides the necessary networking, graphics, and interactivity support, if the language was arcane and had an extensive learning curve, it could not be used in a project which demands efficient simulation development of applets. Syntactically, Java is a not-too-distant cousin of C++ and thus relatively familiar and programmer friendly. Another benefit is the object-oriented nature of the Java programming language which maximized code reuse and encapsulation. Despite the recent unveiling of Java as a language, it is advantageous for software development of the PACER system because it did not require mastering a vast library of objects and methods to perform routine programming tasks, such as the Microsoft Foundation Class (MFC). Java, in its current form, provides more than adequate tools to develop detailed, aesthetically-appealing, animated, and interactive simulations.

Object Oriented Design In Java

Because C++ was developed to promote object-oriented programming [Stroustrup 1991, Jacobson 1995] while maintaining backward-compatibility with C, it is incapable of being a truly object-oriented language. That is, C++ was not designed from the ground-up to be an object-oriented programming language. Rather, it may be more accurately described as an extension of a procedural language, C, to support object-oriented programming design. Java, on the other hand, is a purely object-oriented programming (OOP) language. All Java programs must be written from the perspective of the creation and manipulation of classes. Procedural programming methodologies are not supported. Java does not allow one to create and call functions. All activities in a Java program take place from the perspective of creating the required objects and invoking their public and protected methods and data members.

Java's purely object-oriented focus provided a unique opportunity to the PACER team to evaluate the efficacy of using OOP in a large-scale software development project. Results of 10 months of development confirm that two cornerstones of object-oriented programming: (1) inter-object communication and (2) code modularization and reuse provide the fundamental basis for developing simulation capabilities in an interactive learning environment. Two implementation examples illustrate the advantages provided by each of these facets.

Inter-Object Communication: The TALU (Tiny Arithmetic & Logical Unit)

In this first example we show the advantages and importance of inter-object communication of object-oriented design. One of the first topics encountered by the beginning computer science student is computer architecture. Students are exposed to Boolean logic and its implementation through logic circuits. Several applets were developed to demonstrate the Central Processing Unit's (CPU) internal workings. These applets range in complexity from simple logic gates to a fully operational CPU simulator, the Tiny Arithmetic & Logical Unit (TALU). The TALU [Fig. 1] graphically demonstrates the manner in which computer macro-instructions, such as LOAD, is executed as a series of micro-instructions. Students using PACER can visualize how each of the micro-instruction sets activate a series of control wires in the CPU while an instruction is being executed.

Figure 1: The TALU Applet

When implementing the TALU, it became clear that the usage of inter-object messaging, which allows several objects to communicate in a synchronized manner during execution, was going to be critical to the TALU's implementation. The TALU uses inter-object communication extensively throughout execution by synchronizing events and data between memory, instruction display, the arithmetic and logical unit, and the various place-keeping memory registers. It is the seamless synchronization that results in realistic simulations. For example, when a new macro-instruction needs to be loaded from memory for execution, the TALU's driver object, called FP, requests the instruction (which is stored in the next segment of "memory") from a memory object. The memory object retrieves the instruction and relays it back to FP, which in turn forwards the information to the macro-instruction decoder. The macro-instruction is then broken down into a sequence of micro-instructions, which are displayed on the screen and returned to FP. FP then coordinates the incremental execution of each micro-instruction by communicating with other TALU objects, such as instructing the ALU object to perform an addition operation or requesting the PC to increment the program counter. In addition to the ability to send and receive processing or data retrieval requests, Java classes have their own graphics capability. In theory, an object can be placed on a blank canvas and by following the proper interfaces defined for that object, it can act on its own or can be interfaced with various other objects to serve a particular function in a communicative object environment. For certain events, the TALU applet as a whole needs to refresh itself graphically. Rather than creating a centralized drawing class, the TALU's objects provided the ability to "draw themselves" when requested by FP. This permitted true data encapsulation, allowing each object to exists as its own entity which could operate on its own or alternately upon a request from FP.

Code Reusability: The Turing Machine

In this example, we show the second component of OOP, the emphasis on code modularization and reusability, is best illustrated by a pair of programs developed for the algorithms module of an introductory computer science course. One of the classic methods of instructing students in the manner in which algorithms are translated into computer instructions and subsequently executed is the Turing Machine.

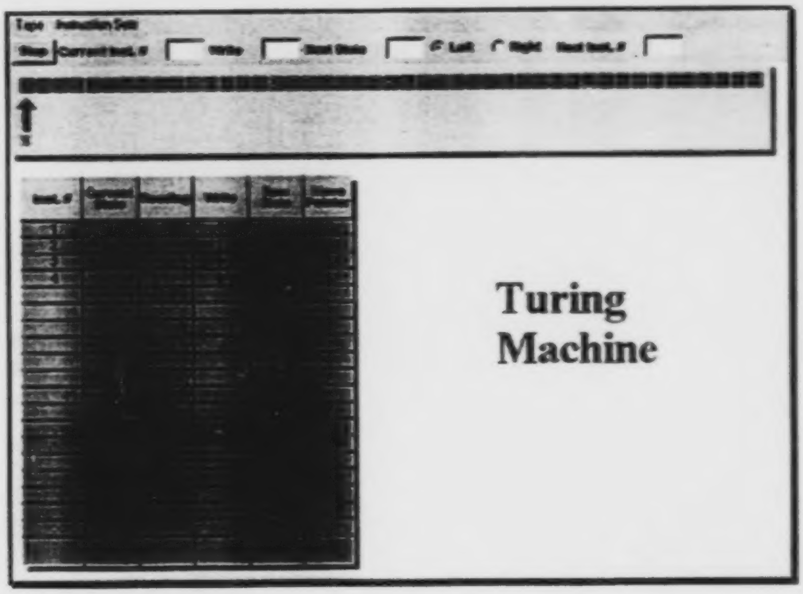

Figure 2: Turing Machine Version 1 (The "Step-Through" Machine)

Two Turing Machines were developed for the PACER project, each serving a distinct purpose in the instructional process. The first machine [Fig. 2] was designed to illustrate for students the basic operation of a Turing Machine, particularly from the perspective of instruction selection and execution. The applet contains a series of simple, pre-defined instruction sets, any of which may be selected by the user. The user must then create a tape and attempt to step through the execution cycle. Before any given instruction will execute, the student must first correctly determine the applicable instruction, the value which will be written to the tape, the pointer's new state, the direction in which the pointer will move, and the next applicable instruction after the pointer has moved. By requiring the student to find the applicable instruction and more importantly, predict the next applicable instruction after the present one executes, a student will be forced to learn the structure and operation of a Turing Machine and its relationship to the instruction set.

The second machine [Fig. 3] was designed to behave more like a "true" Turing Machine. The student must first create an instruction set, create the tape from which the instructions will operate, and then "execute" the program on the machine. This allows the student to develop their own algorithm to solve a given problem and the test the correctness of the algorithm by running it on the intended machine.

When designing the Turing Machines, emphasis was placed upon making the applets as "application-like" as possible. Thus, all editing activities were designed to take place through the use of drop-down menus and pop-up windows, much the same as a "true" application would behave. This created a unique design problem from the outset, since Java applets do not directly support a menu-driven interface. The solution was to create a "master" Java applet which consisted simply of a button, which, when depressed, would display the primary Turing Machine window. Once this initial hurdle was cleared, the remainder of the design process was directed toward general application structure.

Consistent with basic object-oriented design practice, an attempt was made to develop as many general-purpose classes as possible which could be utilized by both machines with little or no modification. It was soon

BEST COPY AVAILABLE

discovered that the fundamental internal workings of the Turing Machine could be implemented as a series of general purpose objects, which required minor modification between machine versions. The basic object hierarchy is similar for each version of the Turing Machine [Fig. 4 & Fig. 5]. The primary difference is the manner in which the Instruction Set class was implemented. In Version 1, the Turing Machine instruction set was predefined and thus relatively simple to implement. However, in Version 2, facilities had to be provided to allow the user to define the instruction set.

In order to maximize code reusability, care was taken to ensure that the Turing Machine's Instruction Set object was in the same format and not impacted by which instruction definition method was selected (i.e. hard-coding for Version 1 & user-defined in Version 2). Thus, the actual InstSet class was not significantly modified between applets. However, in order to facilitate user definition of Turing Machine instruction sets, InstSet was transformed into a derived class of a new object named InstFrame. InstFrame is an extension of a Java Frame object, and essentially creates a pop-up window in which the user may input the required values for a single

Turing Machine instruction. By making the actual instruction set a derived class of the InstFrame object, communication between the values input by the user and placement into the InstSet class data members was facilitated. Again, Java's emphasis on object-oriented design, which by it's very nature maximizes code reusability, made implementation of a fairly complex program much easier than would have been the case using procedural methodologies.

Initial Results and Feedback

As noted above, the PACER team has developed several applets. At present, the primary focus of development has been to demonstrate basic hardware and logic concepts. Thus, Java has been successfully utilized to produce numerous interactive circuit diagrams and memory register representations. One of the most time-consuming, complex and ambitious applets developed thus far has been the "TALU" simulation. The TALU (Tiny Arithmetic & Control Unit) simulates the operation of a microprocessor control unit at its most basic level. Students can design a program using a rudimentary machine language, load that program into the TALU simulator and step through the program's execution. The simulator steps through each of the micro-instructions associated with a macro-instruction, and indicates the data flow path associated with each micro-instruction. Thus, the student can more readily understand the complex interrelationship between memory, CPU clock, program counter, and processor registers.

Another fairly large simulation is the set of two Turing Machines. The first machine helps the student understand the abstract concepts of a Turing Machine's execution and structure. The student selects any of three pre-coded instructions sets and enters starting tape values. Given the current state and pointer reading, the student must predict: (a) what value will be written to the present cell; (b) what the next state of the Turing Machine will be; (c) which direction the pointer will move; and (d) what the next applicable instruction will be. The machine will not "execute" the instruction until the student makes the proper selection. The second machine is more in the nature of a "true" Turing Machine. This interactive simulation requires the student to create and test their own Turing Machine tapes and instruction sets.

Formal testing and evaluation procedures are underway. However preliminary studies reveal that student reaction to the prototype PACER simulations has been extremely positive. Students indicate that they use the PACER system to visualize complex material that can not be easily understood in lecture or in textbook form. They seek to experiment with the interactive capabilities along with gleaning additional theoretical information from the explanations that accompany each of the simulation packages. Approximately 97 beginning computer science students have utilized and evaluated the PACER system.

Conclusion

The interactive learning system called PACER has been under development for less than a year. Although many features of PACER have yet to be implemented, the PACER team is quite satisfied with (1) developing the system using an object oriented programming language called Java and (2) positive reaction by approximately 97 students enrolled in the introductory computer science course. Although Java's recent release makes programming the simulations a challenging exercise, it has provided a wonderful mechanism for attaining the ambitious goals set by the PACER team.

Acknowledgments

We gratefully recognize the efforts by Chad Brown during the initial phase of the PACER project. This research is supported in part by the National Science Foundation grant NSF-CCD 955485.

Abstract: This paper explores one model for developing multimedia and a spirit of cooperation. It is based on a course I taught to 6th graders at the Exploration Summer Program in Southbourgh MA and work I am currently doing at the Isidore Newman School in New Orleans, LA. Each class created a hypermedia game located in a virtual representation of their school. Players of these games travel through the school, interact with "teachers" and "students," and try to solve mysteries. The process of creating this game can be broken up into three conceptual categories. First of all, exercises stressing cooperation prepare the student to work together on the project. Secondly, lessons focusing on the principles of Multimedia Design provide the skills students need to create an exciting game. Finally, students explore of the ways that Hypertext links provide the means to connect individual student efforts into a collective project.

Introduction

New Media combines images, text, video, and sound to produce complex works of art. Successful multimedia projects require the coordinated efforts of many people. Facilitating cooperation between story tellers, visual artists, writers, and musicians is a central concern of professional multimedia developers. This concern is even more pronounced among teachers using computers in their classrooms. After all, a teacher wants more than a slick finished product. S/he must also try to engender a supportive classroom environment where learning and community can thrive.

This paper explores one model for developing multimedia and a spirit of cooperation. It is based on a course I taught to 6th graders at the Exploration Summer Program in Southbourgh MA and work I am currently doing at the Isidore Newman School in New Orleans LA. Each class created a hypermedia game located in a virtual representation of their school. Players of these games travel through the school, interact with "teachers" and "students," and try to solve mysteries.

The process of creating this game can be broken up into three conceptual categories. First of all, exercises stressing cooperation prepare the student to work together on the project. Secondly, lessons focusing on the principles of Multimedia Design provide the skills students need to create an exciting game. Finally, students explore of the ways that Hypertext links provide the means to connect individual student efforts into a collective project.

Cooperation

The game design unit begins by breaking the students into three equal groups: the dreamers, the communicators, and the technicians. The dreamers go outside with a teachers aid. The communicators and the technicians stay in the lab with the instructor.

Once outside, the dreamers are lead on a guided visualization. They are asked to "travel" to a safe, beautiful, far away place. When they find this place they are asked to take a mental picture of it. They must remember what this environment looks like. When all the dreamers have a clear picture in their heads of their imaginary environment, they return to the lab. There is one catch -- the dreamers are blindfolded as they return.

Meanwhile, the communicators and the technicians are discussing the challenge that they face. They learn that the blind folded dreamers have a mental image that they must convert to an image on the computer screen. The dreamers will describe the image that they have in their heads. The technicians are the only people allowed to touch the computer, key board, and mouse. Thus, the technicians must respond to the description given by the dreamers. This gives them a great deal of control, but they are not allowed to talk. That is where the communicators come in. As the technician draws, fills, sketches and follows instructions, the communicators can ask the dreamers questions: Is it a dark green or a light green? What kind of trees are on the hill? etc. The communicator is responsible for making sure the technician gets it right.

When the dreamers return to the room, the students use the computers in pairs of three: one dreamer, one communicator and one technician at each machine. Then the difficult process of converting mental imagery into art begins.

The lesson provokes conversation about technical and artistic themes. It encourages students to talk about how to do complex technical operations (i.e. "go to the tools menu and select the icon that looks like a paint brush"). It also places those technical issues in the context of accomplishing a specific and worthwhile goal (i.e. "in my imagination, the river goes through the forest and there is a tree house in one of the trees") which in turn forces communication and collaboration between students who love technology for its own sake ("techies") and students who only become interested in technology when it helps them accomplish specific goals ("pragmatists").

Students begin to think critically about the different elements involved in creating computer art. One needs imagination, technical ability, and the facility to translate between the two. This demonstration has been an effective means of encouraging students with various learning styles and strengths to become excited about computers. When students begin to work individually, they will have a model for the different elements that are involved in creating computer art. For example, if a technically skilled student is having trouble producing his/her own work, the instructor can tell them that they need to do some dreaming. On the contrary, an imaginative student can be encouraged to work on being a technician by learning various functions of a software program (i.e. "try being a technician for a while, Tom").

Additionally, the lesson encourages and models restraint and sharing. Often, certain students attempt to monopolize the computers. If this happens in the future, I can tell the student, "OK, since you are not letting other people have a turn, you have to be a communicator." This creates specific roles that facilitate cooperation and prevent monopolization by aggressive and technically proficient students.

At the end of this lesson, the dreamers take off their blind folds and look at the image that has been created. Each group can present their experience to the class, and the dreamer can comment on the authenticity of the final product. Discussion will ensue about difficulties, frustrations, and rewards of the exercise. The exercise is repeated with students assigned to different roles. This helps students realize that they can play all of these roles despite their initial proclivities.

Multimedia Design

The next step is to help students develop the conceptual, technical, and narrative skills necessary to develop an interactive game. Story telling is an important element of multimedia design. "Round Robins" are an effective method of encouraging students to tell stories collectively. In a Round Robin, one student begins a story. After a certain amount of time, another student must continue the story. This continues until several students have contributed to the story. This process can be done orally (around a camp fire, for example), or textually. I often lead Round Robins in a computer lab, and have the students move one chair to their left every five minutes. The stories are usually quite entertaining, and students listen carefully for their contribution to each story.

One can adapt the basic Round Robin to mesh with the non-linearity of interactive stories. But before attempting a non-linear story, it is a good idea to complete a traditional, liner Round Robin. Break the class into groups (about eight students in each group). Each group has their own row of eight index cards on the floor and each student has eight more index cards in their hand. The students write a few sentences on the card to start the story off. Then, after a few minutes the students move to their left, using one of their own index cards to add to the story that their classmates started. Eventually, each student will get to write the conclusion to the story that they started. In the end, there are eight columns that constitute eight different stories:

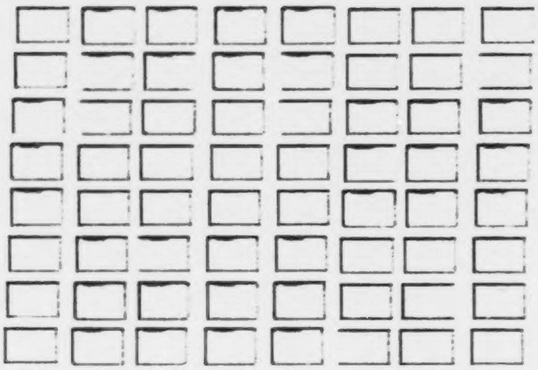

Figure 1: A traditional, liner Round Robin

To read the stories, one would start at any of the top cards and read straight down.

At this point, the instructor can introduce the concept of a non-liner Round Robin with branching choices. This time, a single person writes the beginning of a story on an index card and offers two choices at the end of their story. For example, the first card might read, "Jim is a farmer. Should he plant corn or wheat?" Then a second student has to write two cards, one for corn and one for wheat, and provide two more choices at the end ("All the wheat is dying. Should Jim sell the farm or pray for rain?" or "The corn harvest is bountiful. Should Jim buy a new car or a boat?") This process continues, so that the next student has to make four cards, the next one eight, etc. After completing this exercise the floor will look like this:

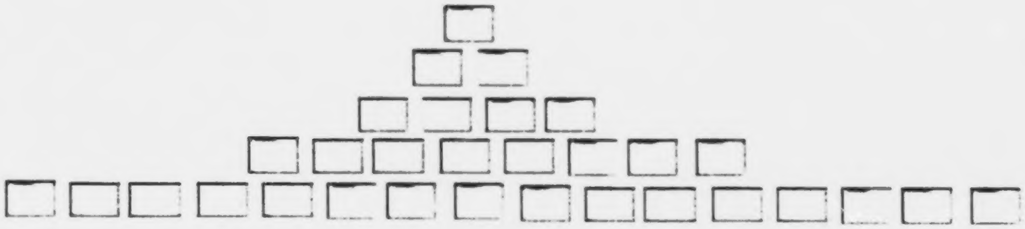

Figure 2: A non-liner Round Robin with branching choices.

To read this story, you would start at the top, and follow any "pathway" down the pyramid.

Clearly, the exponential nature of this process turns the non-liner story telling process into a mess by the fifth generation. The amount of work required to continue the story doubles every generation. Students begin to get frustrated. When students compare the amount of work they spend writing to the amount that people will actually read they become very receptive to alternate modes of developing interactivity.

At this point, the instructor can facilitate a conversation that compares the differences between the linear and exponential stories. Students observations are written on the board and facilitate a discussion on the different modalities of story telling. This distinction will remain relatively abstract at this point. However, this difference applies directly to multimedia design. In programs like HyperCard and HyperStudio, students often run into the same exponential growth problem that resulted from the non-linear Round Robin. Often, students do not understand why it is getting harder and harder to continue their stories. This lesson is designed to give students a concrete, visual experience of exponential growth. This knowledge proves important later when the class begins to create an interactive environment with HyperStudio.

The Round Robin idea is a useful way to explore the different narrative structures one must understand to produce multimedia content. Round Robins are also useful for teaching purely technical skills. Round Robins introduce students to the multimedia authoring program the class will use to create their game. Each student will have their own computer with a copy of HyperStudio installed.
After opening the application, the instructor encourages them to use HyperStudio's painting tools to draw in ten minutes. Then, they move one computer to the left. They add text to their classmate's image. After five minutes, they move left again. This time they are shown how to add sound. They can use a sound from the HyperStudio menu, or record one of their own. When they switch again, they learn how to create a link to another card (complete with a groovy transition effect).

This lesson is designed to get students thinking about how to put images, text, and sound together. At the end of the exercise, we can go around the room and experience every multimedia creation. Afterwards, we discuss which projects are effective, and why. Because the projects were produced by several people, criticism is possible without seriously hurting people's feelings. This provokes serious discussion about which techniques are most effective. Even more importantly, this exercise systematically introduces the students to HyperStudio which we will soon use to create our game.

Before we begin working on our game, we need to solve the problem of exponential growth that was identified earlier. We do this, in part, by reviewing successful commercial games. All the students evaluate existing games. MYST serves as our primary example of a successful interactive story. Like many games, MYST avoids the pitfalls of exponential growth by relying on strong spatial metaphors. The story takes place on an island so the narrative is constrained within a clearly defined domain. The user of the game does not feel constrained because it seems natural that islands are spatially bound.

MYST provides an opportunity to sing the praises of place-specific story telling. As the students begin to work together to create a collective story, they are encouraged to develop and map the location in which the story will unfold. The school site provides a familiar location and allows students to reflect upon and position themselves within their school environment. Creating novel and creative stories within the walls of ones own school can be an effective way for students to map their own place within the larger school community. It is also possible to have the action take place in a haunted castle, a sunken ship, an historically important place, or a prominent location in the school's neighborhood. What is important is that spatial metaphors are constraining and enabling the project's development.

In order to ensure that all students are "at the same place," it is important to construct a large, communal map. This map can be loosely based on the map of the school site. It should be large enough so that ten kids can stand around it and see it at the same time. Once the map is constructed, students need to break up the work of constructing the game. They should write their names on the portion of the map that they wish to build in HyperStudio. As they work, they will begin to identify the students who are working on rooms or hallways that connect with the area they are building. As they work they will need to consult with each other and the map to make sure their visualizations are compatible. At this point, however, they do not link to each other. It is enough to construct a navagatable room in which a user can turn in various directions. Students are challenged to visualize and simulate three-dimensional space.

Hypertext: Linking it All Together

Hypertext facilitates the dynamic linking of diverse media. In the context of this project it allows students to connect their individual work together to create a collective project. In this respect, hypertext facilitates a happy marriage between individual expression and participation in collective life. The World Wide Web is one example of this. Individual pages are linked together to create a globally accessible information resource. Pages created by different authors in different parts of the world can be included on the same "links page" and form a resource for a community of scholars or hobbyists.

In my class, students utilized hypertext to connect their work to their classmates work. An intense period begins where students begin to "link to each other." Eventually, the whole game ends up on a single hard drive. This requires flexibility and cooperation. Students must adapt their individual creations to the specifications of other students work. Hallways must lead to doors, sections of courtyards must be connected together, and secret passage ways need to lead to somewhere interesting. The spirit of collective accomplishment makes changing personal work bearable.

Conclusion

When everything is linked, the beta version of the game is completed. Using the local network, the game is copied onto all of the hard drives in the lab. Working together, the class created a quality control rubric that we used to evaluate the Beta version of the game. Everybody plays the game while looking for bugs. When someone finds a bug they fix it on the master copy of the program. At least two class periods can be spent debugging. When this process is finished, the 1.0 version is ready for release. Once again, all of this is copied onto all the hard drives. This time, however, members of the larger school community are invited to play the game. This allows parents, administrators, and other students to experience the multimedia extravaganza that the class has created.

Feedback from the school community may result in a few suggestions for improving the game. After these are completed, it is time to compress the game into an installer-maker. These are available commercially and as shareware. The game should fit on 2-5 disks that can be installed on a hard drive in the same way you would install commercial software. By adding custom disk labels, your class can produce an extremely professional-looking piece of software. Your students will have something that they can be proud to take home to their friends and family. More importantly, they will feel a sense of ownership in a collaborative project that connects them to their class and their community.

The User Interface Design of Learner-centred Interactive Multimedia Programs

Abstract: This paper discusses some issues in the user interface design of learner-centred Interactive Multimedia (IMM), illustrated by a case study of the development of SarcoMotion, a program about skeletal muscle contraction in first year tertiary Human Biology. A constructivist approach was taken to the design of the educational material, and some of the instructional design issues are discussed, in particular, how to achieve a learner-centred environment. The paper also discusses various issues in the design of a user interface which could allow students access to the content in appropriate ways, so they could easily make their own cognitive links.

The development of the IMM program was based on an incremental prototyping model, and this paper traces the evolution of the user interface, based on the educational context in which it was to be used.

Introduction

All students doing Health Science courses at Curtin University complete a first semester unit in their first year which covers basic concepts of human biology, including cells, tissues and the musculoskeletal system. Students are enrolled in a variety of courses, including Nursing, Physiotherapy, Medical Science, Pharmacy, Environmental Health, or are completing an undergraduate Science degree. Students have a range of backgrounds, and diverse skills and confidence levels must be accommodated. For example, some students have good chemistry and physics skills, while others have none at all. Furthermore, many are part-time students, and fit their classes in around work and/or family commitments. Some students also come to the unit with low levels of confidence in learning, and lack the assertiveness which will allow them maximum gain from their tertiary studies.

The unit has a large enrolment of approximately 800, and teaching is by mass lectures followed with much-repeated tutorial sessions in groups of up to 20. The latter are often staffed by part-time tutors and consistency is not always possible.

One week of the unit is about muscles, and, in particular, skeletal muscle contraction. The molecular basis for skeletal muscle contraction is complex and challenging, requiring understanding of dynamic and three-dimensional processes at the sub-microscopic level. The students need to be able to visualise the process of contraction, and understand how the process is controlled and co-ordinated, rather than rote-learning a sequence of events.

Students had obvious learning difficulties in understanding this process in the traditional, teacher-centred approach to the topic. Students could identify the various components, but failed to appreciate the scale of the components about which they were learning. The major learning difficulties were twofold:

- Students had difficulty in visualising what was happening.
- Students had difficulty understanding the complex interactions between the components of the muscle cells.

Interactive Multimedia has advantages over traditional educational media with regard to visualisation of three-dimensional, microscopic and dynamic processes [Phillips 1996, Chapter 1], and it was seen as an appropriate technological solution for the first learning difficulty. The hypermedia aspects of IMM also indicate that it is an appropriate medium for learning about the complex interactions in the process.

A pragmatic, two-stage approach was taken to solve this real teaching and learning problem. Firstly, an animation of the muscle contraction was prepared as a QuickTime movie for use as a presentation aid in the large-lecture situation. A frame of the animation is illustrated in [Fig. 1] of the electronic version of this paper. Secondly, an IMM program was developed as a self-paced resource for use in small group tutorials, so that students recognise the animation they have seen in the lecture and can explore and question it in a less-threatening environment.

The animation, and the ability to control its progress, were found to be very effective means by which the lecturer could enhance student understanding in the lecture situation. However, the purpose of this paper is to describe the development of the interactive multimedia program, SarcoMotion, of which the QuickTime animation was a part.

Instructional Design

As stated above, the dynamic and molecular nature of the process of muscle contraction made interactive multimedia an appropriate tool for visualisation of the process. As well as visualisation, students need to understand how the individual components of the process interact with each other. That is, they have to develop their *own* mental model of the process, and therefore, a learner-centred approach was adopted in the instructional design of the content.

It was not appropriate to use the traditional, objectivist-based approach [Marra 1993] to instructional design in this project, because it is inherently teacher-centred. Also, as pointed out by [Laurillard 1993], "the analysis into components of the teaching-learning process is not followed by any synthesis". The students were already learning about the components - what was lacking was the synthesis of the components into an understanding of the whole.

Instead, the learning problem suggested that a constructivist approach [Marra, 1993] was warranted. A learning environment was required which guided and supported students in their efforts to develop their own mental models and understanding of the learning task.

The material had to be structured in a non-linear fashion in a way whereby students could construct their own meanings and make their own links. However, care had to be taken that the design did not result in a discovery learning environment, where students were left to sink or swim in a sea of information. [Laurillard, 1994] has noted that discovery learning environments can hinder learning because it is assumed that students have good research skills and can find their way through the material. Good students may have these skills, but weaker ones may not.

Laurillard's desideratum is a guided discovery learning environment, where the learner has freedom and control over their activities, but where guidance and scaffolding are provided to the learner to give them a context in which to work.

In the particular teaching situation where this program was to be used, the context of use of the program was clearly defined. The use of the animation in lectures gave students a clear starting point, and a thorough unit outline provided the learning objectives. This reduced the amount of guidance needed to be provided by the computer.

Learner-centred Design

Experience with a number of previous development projects has indicated that traditional linear or hierarchical structures of lesson content [Phillips 1996, Chapter 4] are not appropriate when trying to implement a constructivist approach to learning. The traditional approach uses structured reasoning to build up an argument. That is, one starts at the beginning, and build up arguments one at a time until the final structure of knowledge is revealed. This approach is deeply ingrained in any scholarly pursuit, and is not to be denigrated in terms of coming to an understanding of complex issues. However, structured reasoning is an author-centred approach to knowledge. Transferred to the teaching situation, it is a teacher-centred approach to learning.

If one seeks to design for student-centred learning, an environment needs to be created which encourages research-type activities. That is, an environment wherein the student can access many pieces of information in any way they like, given appropriate guidance, so that they can create their *own* structured argument based on their *own* analysis of the content which they have discovered.

An appropriate design approach for this purpose has been found to be to start with a visualisation of the process as a whole [Phillips 1996, Chapter 4], allowing students to explore as they wish, initially browsing to get a 'feel' for the contents, and then delving into various parts of the content to the depth required. Unlike the traditional approach which starts at the beginning and builds up to a conclusion (the end), this approach starts with a representation of the total process (the end), and allow the student to work back to whichever beginning is appropriate to them.

Structure of the Content

Given the arguments in the previous section, it was natural that the animation of the muscle contraction process was the starting point for student interaction.

The first level of interaction is observation., where the student can observe and manipulate the animation by using the standard QuickTime movie controller. Moving the mouse over parts of the animation identifies components and students can observe how the components interact with each other.

The second level of interaction is *interrogation*. When satisfied with observing the process, students may wish to inquire further into individual components. They may choose one component and find out about its role and interactions, or they might choose an interaction or event and see how each component contributes.

In designing the second level content an effort was made to ensure that it was not textual, linear and didactic. A related design criterion was not to impose the designers' learning behaviours on the users of the program. Instead, an attempt was made to approximate real tutor-student interaction, as identified in Laurillard's [Laurillard 1994] Ideal Teaching Learning Process. This was achieved by analysing the questions which students typically asked of lecturers and tutors, and using these questions as the means by which the students interrogated the information. These ten *questions* are shown in [Tab. 1].

Analysis of the content also indicated that there were eight independent *topics*, corresponding to components of the animation [Tab. 1], and the ten questions could be asked of each of the eight topics. There were thus eighty nodes of information, in addition to the basic description of each topic.

The underlying structure of the content could therefore be modelled by a concentric structure, as shown in [Fig. 2]. Each topic is described by a wheel, with the basic description of the topic along the axis, and questions at the rim.

	Questions	
What is it made of?	Where does it come from?	How big is it?
What does it do?	Where is it made?	How does it work?
What does it interact with?	Where does it work?	Why do you need it?
What controls its activity?		
	Topics	
Thick Myofilaments	Myosin	Troponin
Thin Myofilaments	Actin	Ca^{2+}
	Tropomyosin	ATP/ADP

Table 1: Basic subject components of the Sarco*motion* program

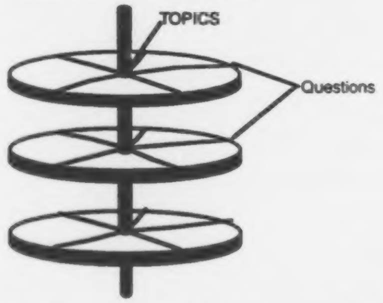

Figure 2: The concentric information structure which can be used to model the content of the SarcoMotion program.

User Interface Issues

[Cooper 1995, Chapter 5] distinguishes three types of user interface paradigms: the "technology paradigm", the "metaphor paradigm" and the "idiomatic paradigm". The technology paradigm is based on the way the program is constructed, rather than on what the user wants to get out of it. Almost all old computer programs had such a user interface. In the IMM sense, if the content had a hierarchical structure with topics and sub-topics, it would be implemented as a series of menus leading to content screens.

The metaphor paradigm attempts to display the interface in terms of some recognised, real-world, visual representation (e.g. the Trashcan on the Macintosh). However, the use of metaphors often restricts the design of the interface, because desired functions are forced into certain forms in order to fit the metaphor. As [Cooper 1995, p54] says: "Most metaphors firmly nail our conceptual feet to the ground, forever limiting the power of our software".

The idiomatic paradigm is based on learning how to accomplish things. It is a simple representation of what the program is to achieve, which users can learn naturally. The idiomatic paradigm is not based on any real construct, but rather on a convenient representation which suits the purpose. A simple example is a window close box.

In SarcoMotion, the animation of the muscle contraction process is the idiom of the user interface. The animation is a visualisation of the entire process, and students are familiar with it, having seen it projected in lectures. Users interact directly with the moving representation of the process, rather than by externally imposed menus or metaphors. The observation level (Level 1) *is* the idiom.

The interrogation level (Level 2) can be easily reached by simply clicking on the moving animation. Depending on which component the user clicked on, the user navigates to the basic information on that topic. That is, to one of the eight nodes shown schematically on the axis of [Fig. 2].

However, once within the level 2 structure, a separate user interface mechanism was required to move between the information nodes. This part of the user interface design occupied most of the time of the design team.

A further criterion in designing the level 2 information was that context be maintained with the animation while the learners browsed to other parts of the second-level information structure. A related decision was that students should have access to the full range of questions and topics at any time in level 2.

A particular advantage of this design is that students can access any piece of information in the program with two mouse clicks: one to go from the animation to the axis of the information wheel in [Fig. 2]; and another to move from the axis to the circumference.

Navigation through the material is natural and direct. To explore a topic, users click on the object in the animation; to explore a question, users click on the question. Because users are interacting directly with the content, by clicking on the object they are investigating, they are creating a cognitive anchor by which to remember the information, and knowledge acquisition is likely to be higher. This approach can be contrasted to the common approach where navigation is by contrivances such as arrows and buttons with names such as 'menu'.

The concentric information structure allows hyperlinks between nodes in a way whereby students are less likely to get lost in hyperspace.

While the points above indicate some theoretical advantages to the chosen design, it was by no means a simple task to actually implement a user interface which encompassed all of the design decisions made. Several prototypes were developed, tested and improved before the final design was agreed on.

Evolution of the User Interface

Version 1

An initial prototype was used to determine the feasibility of the idea of clicking on the animation. In an ideal situation, clickable hot spots would have to be created for all components of the complex animation, for each of the 70 frames. This was not practically feasible. Instead, when users stopped moving through the animation to investigate, it jumped to one of six key-frames, which were essentially still images on which hot spots could be placed.

Testing of the first prototype was done by peer review within the development team.

Clicking on a hot spot took the user to a new screen, as shown in [Fig. 3] of the electronic version of this paper, with one whole screen per information node. While a shadow was used to give an appearance that this screen 'sat' in front of the animation screen, no part of the animation was visible. The only context available to the learner was the image at the bottom right, which showed the part of the animation which had been clicked on. Students could move through the second level information space, learning about individual components, without returning to the animation to obtain an understanding of the process as a whole. This user interface clearly did not satisfy the educational goals of the project.

In designing a mechanism whereby students could access the ten questions, the design team sought to avoid a situation where students could sequentially work through the questions. The questions were divided into 4 categories (what, where, how, why) and displayed with a 'spinning top' idiom, shown at the bottom left of the electronic [Fig. 3]. On entering a level 2 screen from the animation a random choice of question was made by spinning the 'top'. This mechanism appeared to be successful.

Students could only get to another topic by returning to the animation, or occasionally by clicking on hypertext links.

As more content was developed to put into this interface, it was found that some answers to some questions could be answered very briefly, and a full screen was too large for the small amount of information. There were also technical problems with creating hotspots: the number of invisible objects required would have been very tedious to create, and would have severely impacted on the performance of the authoring environment used.

Version 2

A solution for the hotspot problem was achieved in the second prototype by developing a customised external command which identified the colour of a pixel on the screen and used a small database to find which topic corresponded to which colour.

An attempt was made to resolve the lack of context to the animation by using smaller content screens overlaid directly on top of animation. To avoid the problem of varying length answers to questions, all answers for a given topic were combined into one screen which could be scrolled like a world-wide web page. The 'spinning top' idea was rejected, and all topics and questions were visible at all times at the top of the content window, with scrolling content below it. A representative level 2 information screen from the second prototype is shown in the electronic [Fig. 4].

An advantage of having all questions and topics available at all times was that an extra dimension of navigation was possible. In Version 1 (neglecting hypertext links), the only way to get to another topic was to return to the animation (equivalent to returning to and moving along the axis of [Fig. 2]), and then choose another topic (moving to another 'wheel'). In version 2, in addition to moving around the wheel to other questions, it was also possible to navigate perpendicularly, from a question on one wheel, to the same question on another wheel.

Version 2 was tested in normal classroom use and formatively evaluated by student questionnaires and by observation of student use of the program by members of the development team. Some significant problems were found:

- Because the second level content directly overlaid the animation, users thought that the content was the main part of the program, and the animation was secondary.
- Having all the topic and questions continually visible made them behave exactly like menus, and students tended to move linearly through the topics and questions.
- Despite our initial intentions, there was too much text on screen. This was caused by combining answers from all the questions for a given topic into a single scrolling field. Also, more graphics needed to be developed to complement the text.
- Some technical problems with the implementation meant that different parts of the information screen behaved differently at different times. Mouse clicking was not consistent. The mechanism for scrolling through the text by dragging with the mouse was not intuitive, and also clumsy to use.

The design team met again and tried to resolve these problems.

Version 3

The first decision made was to once again separate content into screens with one topic/question per screen. The content screens could thus be made even smaller. The second decision was to offset the content screen from the animation, so that the main animation is always visible, as shown in the electronic [Fig. 5].

The fact that the animation window is always visible behind the level 2 information means that the student can always see where they are and where the topic fits into the context of the whole process.

The ability to choose any question or any topic from a given screen was retained. However, the topics and questions were now hidden in popup menus, in an effort to prevent students moving linearly through the material. The spinning top from version 1 was also reinstated in a modified form. Students could use the spinning top to randomly choose a question.

The level two content also contains links to glossary information, shown in the electronic [Fig. 5] by the underlined G-actin. Topics are also linked where relevant by hot words such as 'thin myofilaments' in [Fig. 5]. Clicking on a hot word takes the user from the node to the appropriate topic on the axis of the concentric structure.

There is thus a very rich navigational structure, with formal links in two dimensions (horizontally and vertically in [Fig. 2]), and hot links where relevant between topics. However, the navigation is achieved by direct interaction with the content, without recourse to artificial constructs, such as navigation buttons.

A further advantage of the concentric content structure and the navigation scheme used in version three was that it is possible to get to every piece of content in level 1 and level 2 with two mouse clicks.

The user interface used in version three was observed to run very effectively with students in their normal classroom situation.

Conclusion

The design decisions made in developing this project were specifically aimed at producing a learner-centred, constructivist learning environment. After the design decisions had been made in principle, considerable effort had to be made to produce a user interface which met the design guidelines, while at the same time providing an intuitive experience for the student. It would have been impossible to arrive at the final product without developing and formatively evaluating a series of prototypes.

The next phase of the project is a formal summative evaluation of its educational effectiveness to be conducted in 1997.

Acknowledgments

The authors wish to thank Angela DiGiorgio for her graphic design work in this project, in particular for her creation of the animation of the muscle contraction process. The Sarco*motion* program was developed using Allegiant SuperCard 2.5. The animation was developed using Macromedia Director 4.0, and saved as a QuickTime movie for manipulation.

Abstract: This paper describes the process of making an animation of the Great Hall of the Austrian National Library in its current and a reconstructed historical state. This animation was created at the Institute for HyperMedia Systems of Joanneum Research, Graz, based on a digital three-dimensional model, which was built by the Institute for Computer Graphics of Graz University of Technology. After description of the modeling process, we take a look at the various steps involved in building the animation: from definition of motion paths, lighting scenery, to rendering issues and image post processing, which prepared the data for recording onto a CD-I. Finally we describe the adaption of the 3D model for an interactive walk-through as done at the IICM of Graz University of Technology.

1 Introduction

The Great Hall of the Austrian National Library, located in Vienna, is a famous baroque building, designed by the architect Johann Bernhard Fischer von Erlach and his son Emanuel. It was built in the years 1723–1726. In the center of the hall, a larger than life-sized marble statue of Emperor Karl VI. honours the patron of the building. The entire hall is 77 by 28 meters in size, and the impressive oval dome with frescos by Daniel Gran gives the building a total height of almost 30 meters. The book shelves along the walls hold over 200 thousand volumes (mainly from the 16th and 17th century) of the total 6.7 millions of books, papyri, letters, and carthographic material of the National Library.

Under order of the Austrian National Library, the entire Great Hall including the statue was modeled geometrically and photographed to create a computer model whith photorealistic texture mappings. The model of the Great Hall consists of about 68000 vertices, 19000 faces, and 170 texture images. The modeled statue has additionally about 7000 vertices and 12000 faces.

The advantage of creating computer animations of the scene over an ordinary video film is the possibility to create a realistic view of the historical state of the Great Hall, without the columns and arches built later for statical reasons, just as if it still existed today. Thus an effective visual comparison between the historical and the current state is possible via blending the two models one into the other. Moreover the virtual camera allowed extreme views which would have been difficult to realize with a film camera.

Of course realistic rendering of the model was very crucial, however it was decided to make the computer generated data set visible at some places by means of wireframe animations—and also still images as background for menu screens—in order to emphasize the fact that the animation was computer-generated.

2 Modeling the Great Hall

The modeling was done at the ICG (Institute for Computer Graphics and Vision) of Graz University of Technology.

The base material for building the CAD model of the Great Hall consisted of architectural plans, historical maps and drawings, photographs, and manually measured distances. Characteristical for the baroque building is the large number of architectural details, all of which had to be modeled. The original

BEST COPY AVAILABLE

CAD model was created with the "AutoCad" software package and then transferred to the Model Editor "Medit" for further manipulation. A wireframe drawing of the CAD model can be seen in [Fig. 1].

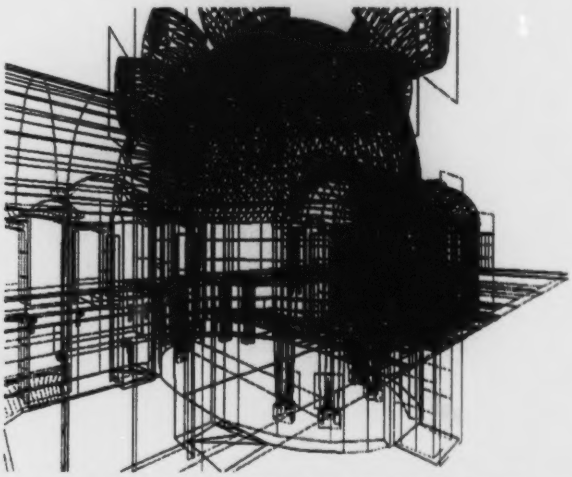

Figure 1: Model of the Great Hall (Wireframe)

170 photographs were taken especially for the purpose of texture mapping. The film was scanned at 1250 dpi resolution. Given the scale of the photographs in range 1:300 and 1:500, this led to a pixel accuracy of less than 1 cm. The sampling of the images to resolution 512 x 512 and 1024 x 1024 preserved a pixel resolution of about 2 cm. A color correction was necessary to compensate the different lighting conditions under which the single images were taken.

To map phototexture onto the geometry, image processing steps were necessary to ensure correspondence of the texture map and the underlying geometry. This had to be done to avoid distortion effects, using software tools created at the ICG. After fitting the images to faces of the CAD model, the images had to be corrected to fit well together where they touched each other. See [Gruber et al., 1995] for more details about this process. This is obvious in the dome which consists of 11 texture images that must match to each other without visible seams.

The reconstruction of the historical state was made based on historical maps and drawings. Missing textures had to be substituted with photographs of similar objects. [Fig. 2] shows two rendered images of the historical and current state of the Great Hall.

2.1 Modeling the Statue of Emperor Karl VI.

The marble statue of Emperor Karl VI. in the center of the Great Hall was modeled using photogrammetric techniques. Images taken from measured positions including reference points were the base for calculating a set of 7000 vertices. The position of these points in 3D space was accurate with a tolerance of only 2 mm. The points were then connected with a set of over 12000 triangles to define the surface of the statue. Manual correction of the automatically generated triangle set was done.

Six of the 20 photographs were then used as texture images. Correction of mapping onto geometry as well as fitting them together, including color correction (mainly equalizing brightness) was done the same way as for the Great Hall. [Fig. 3] shows the statue of Karl VI. as wireframe model and as textured object.

3 Creating the Animation

The animations were created at HMS/IICM with the software package "Wavefront Advanced Visualizer" [Wavefront Technologies, 1991]. After taking over the CAD model of the Great Hall and the Emperor

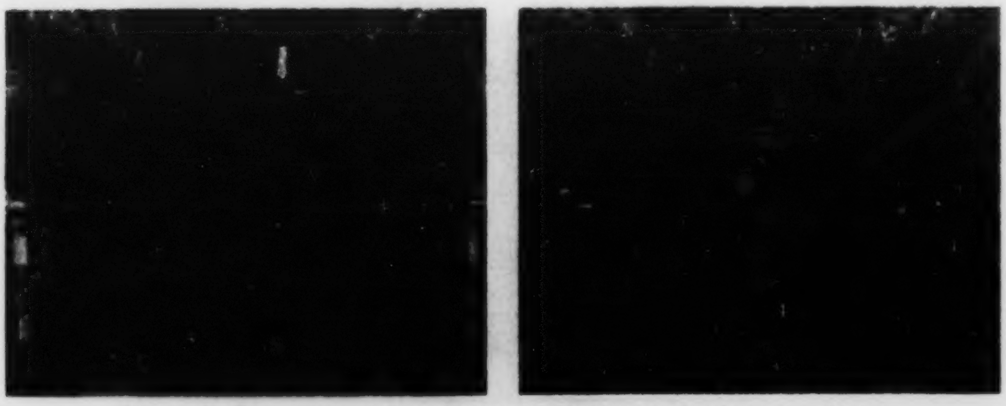

Figure 2: Comparison of Great Hall, before (left) and after Alteration (right)

Karl VI. from the ICG, and some additional processing steps on the geometry the main point is to define appropriate camera paths and a lighting model. Finally the rendered images were prepared ready for recording onto a CD-I, and MPEG movies have been created for viewing the scenes.

For transfering the geometry data from the ICG, we chose the Inventor format [Wernecke, 1994], which can be written by Medit and easily converted to the Wavefront object file format with tools written at IICM. Postprocessing steps like welding of identical vertices and generation of vertex normal vectors could be done via Wavefront command scripts. The geometry model was handled with the "Model" program, surface properties (colors, textures) were defined with "Property".

For the wireframe animation sequences the geometry model had to be reduced in its complexity to emphasize the geometry and to avoid the image being cluttered with lines. The main part of this work was done manually by substitution of geometry with simpler parts, stressing the outlines. To some extent tools for simplifying the geometry automatically could be used: one function merges adjacent triangles into rectangles (used in the dome), another one merges adjacent polygons with an angular variation unter a given threshold to simplify curvatures.

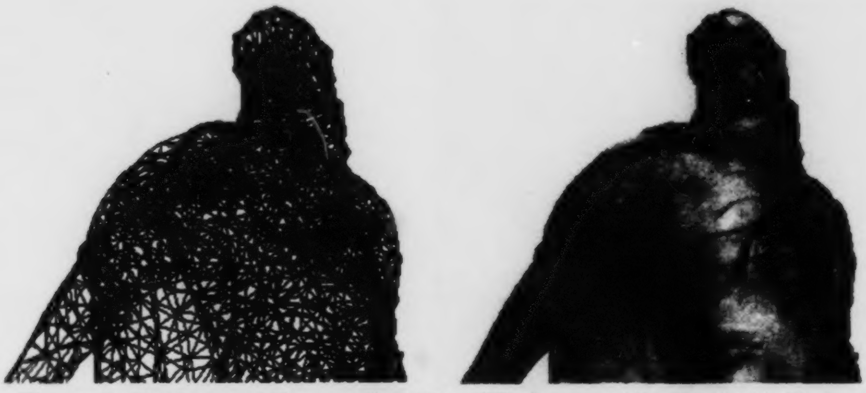

Figure 3: The Statue of Emperor Karl VI. as Wireframe and Rendered with Textures

Placing the single geometry models all together in one scene and creation of animation was done with the "PreView" program of "Wavefront". The definition of camera motion paths and positioning of light sources was also done with this program.

The camera motions of the animations were designed by a director to fulfill several purposes: giving

BEST COPY AVAILABLE

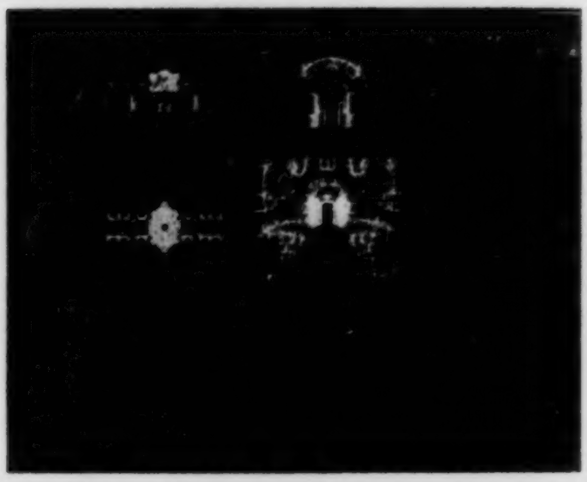

Figure 4: Defining an Animation through the Great Hall (Working View)

an overview of the architectural structure, giving views how the emperor saw the building with his eyes, zooming into interesting fresco details, and, last but not least, comparing the current state of the hall with the original, historical state. [Fig. 4] shows creation of an animation by defining the motion path in "PreView".

For the National Library 11 full-textured animations with a total length of 5216 frames (that corresponds to 3 1/2 minutes of continuous motion) were created, along with 2 wireframe sequences with 315 frames. Test renderings of single images are possible at any time for controlling the lighting scenery and image clipping, whereas rendering of whole animation sequences was done with batch jobs calling the "Image" program. [Fig. 5] shows the playback of an MPEG-movie of an animation sequence. The player shown here includes a software MPEG decoder, real-time check of the motion sequences was possible on a PC with hardware MPEG decoder.

Figure 5: Viewing a Final Animation of the Great Hall (MPEG Movie)

The wireframe images [Fig. 1] required an additional anti-aliasing step [Foley et al., 1990]. The quality

BEST COPY AVAILABLE

of the standard output had severe aliasing and the line width could not be controlled, so rendering was done in Wavefront's plot-format instead. These files were rasterized in a larger resolution and multiple line width (with tools written at the IICM) and then scaled down to the final size. Several tests showed a factor of 2.5 times width and height to be appropriate.

3.1 Technical Data

As mentioned earlier, the amount of data that had to be handled was quite large, to achieve the desired degree of realism. The model of the Great Hall consists of about 19000 faces and the statue of Emperor Karl of about 12000. The texture images were processed at a resolution of 512 x 512 in general, using 1024 x 1024 or 2048 x 2048 in sensible areas like for the statue and in the dome. The total memory demand for storing just the texture images is about 100 MB.

All frames of the animation were rendered in PAL resolution (720 x 576) to allow also for the production of a video with 25 frames per second. Each single rendered image took about 1 to 1.2 MB storage caused by the detailed contents. That results in about 600 MB image data for a 20 second motion sequence (500 images). For comparison: a movie in MPEG format and reduced resolution (352 x 288) of such a scene could be compressed down to 3 MB.

It took about 5 to 10 minutes to render one single image on the SGI Onyx (12 to 20 on an older machine used previously), meaning the ability to render 3 to 5 seconds of an animation per day. The computation time largely depends on the complexity of the scene (whether the statue was rendered in it, number of visible polygons). For test purposes (defining the motion path and controlling image clipping) sequences were rendered in lower resolution and quality (no anti-aliasing and filtering, smaller texture images), which took about 1 or 2 minutes per frame.

The shadows visible on the floor tiles were created by applying them onto the floor texture instead of rendering parameters. A realistic lighting model would require radiosity methods, ray-tracing can only give approximations. However such techniques are too computationally intensive to be applied for the amount of data that was dealt with. Reflections were already part of the phototextures and thus were not necessary to create on rendering. For generating a motion blur effect in one of the animations, three times more images were rendered for this scene and composed (averaged) afterwards.

4 Interactivity

Whereas the final movies of the animation sequences can be viewed on many machine types in high quality (like CD-I players or Multimedia PCs), they restrict the viewer to follow a predefined path through the model. These paths were created carefully to emphasize architectural details of the building and to interpret views of the emperor.

On the other hand users wish to overcome the limitation of a predefined motion, and wish to explore the building in a personal way. The 3D computer model offers the possibility to walk interactively through the architectural model.

Thanks to VRML, the Virtual Reality Modeling Language [Pesce, 1995], a common file format for describing 3D scenes on the net, it is possible to offer 3D computer models on the WorldWideWeb or with Hyper-G, which can be viewed on a variety of platforms. One such VRML viewer, VRweb [Pichler et al., 1995], is developed at the IICM.

Obviously, an interactive walk-through in real-time (at least 10 to 20 frames per second) cannot offer the same image quality as the prerendered images of the animation (which took up to 10 minutes per image to render). Only high-end platforms (e.g. SGI Onyx [Akeley, 1993]) allow interactive navigation in real-time in acceptable quality, even on a model with less detailed geometry. [Fig. 6] shows an interactive walkthrough through the VRML model of the Great Hall, displayed with VRweb.

The CD-I technology chosen for this project made it possible to present the full detail of the photorealistic rendered animations, still allowing interactive navigation by means of menus and cross linked data sets, where the animation sequences are embedded into a trilogy of CD-I's representing the construction, history, and present of the National Library by means of text, images, sound, video, and animations.

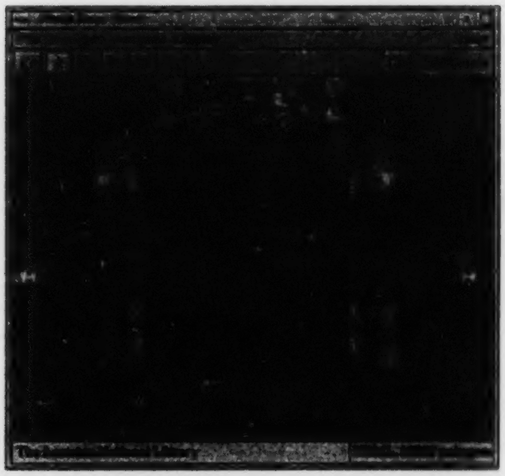

Figure 6: A Textured VRML Model of the Great Great Hall

5 Conclusions

Creating animations of the Great Hall of the Austrian National Library with a high degree of realism required a detailed model, high quality textures, and sophisticated modeling and rendering techniques. The individual steps for creating the model and building the animation were discussed. The model and the animations serve as a documentation of the baroque architectural highlight.

The technological progress allows more and more larger models to be rendered with even better techniques like recursive ray-tracing and radiosity etc. for realistic light and shadow effects. On the other hand, the demand for interactive views of large, realistic 3D models, where users are not restricted to predefined camera motion paths, is increasing. The experiences obtained on building the model and the animation will form the basis of further investigations in this area.

We want to thank all people involved into this project at ICG, HMS, and IICM. Further thanks go to all cooperative people at the National Library and Houdek & Kurek.

Parts of the project documentation, a few sample animations and images, as well as 3D models in VRML format, are available online at `http://www.iicm.edu/natlib/`.

Distance Learning in Multimedia-Networks: a Finnish National Multimedia Project

Seppo Pohjolainen, Heli Ruokamo-Saari
TAMPERE UNIVERSITY OF TECHNOLOGY
Digital Media Institute/Department of Mathematics
Hypermedia Laboratory
PO Box 692, FIN-33101 TAMPERE
Finland
Tel. + 358 3 365 2111, Fax + 358 3 365 3549
E-mail: Seppo.Pohjolainen@cc.tut.fi, Heli.Ruokamo-Saari@cc.tut.fi

Abstract. This paper discusses a project called Distance Learning in Multimedia-Networks, a part of the Finnish National Multimedia Programme. The project started on the 1st of February, 1996 and it joins the efforts of Finnish telecommunication companies, content providers, publishing houses, hardware companies and educational institutions to develop open and distance learning. In this paper the project's background, development and research work, the project's organisation and essential results during project's first year are presented and future developments are outlined.

1 Introduction

The Finnish Multimedia Programme (FMP) (*http://www-tre.research.nokia.com/*) supports the Finnish communication, media and telecommunication industry and improves the field's international competitiveness in the area of telecommunication and terminal technologies, and in developing and taking into use of new infrastructures, in research and development and in producing contents and services for multimedia networks. The Distance Learning in Multimedia-Networks project (*http://matwww.ee.tut.fi/kamu/*) that belongs to the Finnish Multimedia Programme joins the field's technical and pedagogical research centres and institutions that provide distance learning, hardware, software and content producers and telecommunication enterprises in an extensive joint project. The budget of the project is approximately 2 million Finnish marks per year (400 000 USD). The aim of the project is to develop technically and pedagogically useful methods for distance learning that utilise networks and multimedia. Development of fast networks (e.g. ATM) makes it possible to carry out real time and interactive distance learning. Teachers and students, courseware and departments may be geographically situated in different units. Tele-teaching may involve classes, personal computers or workstations and teacher and student can communicate via the network. [see Pohjolainen & Ruokamo-Saari.]

Hypermedia courses will be constructed to be used on a computer - these courses support spontaneous, experimental way of study. WWW-type of platform independence makes it possible to utilise hypermedia-based courseware anywhere Internet is available. Personal computers with multimedia properties are effective in processing and receiving information in the form of text, sound and video signals. Multimedia in distance learning has an essential role in the European Union's 4th stage research programme, especially in the telematics programme. Telepresence and learning environments or microworlds in education has risen to be an internationally important field of research and development. Distance learning using multimedia is exploited by schools, educational institutions, adult learning, private students and enterprises.

2 Project's Development and Research Work

In the Distance Learning in Multimedia-Networks project learning environments are studied and developed from three points of view; telecommunications (hardware), hypermedia (courseware) and pedagogical. The structure of the learning environments is designed to be suitable for different learning situations and for the use of different media as well. In addition to this methods and tools are developed (software) to easily work up and convert existing material (e.g., text, pictures, animation, video) to be used in a learning environment. Students can communicate with the teacher, enrol for courses, receive personal guidance and feedback, pass examinations and receive results.

The usability of the learning environments is developed in various kinds of learning situations in different kinds of transmission and reception environments. Testing is made with various kinds of participants in connection with pilots that are put into practice during the project. Feedback from pilot experiments is used for further development of learning environments.

2.1 Designing of the Learning Environment

2.1.1 The Learning Environment

Designing the learning environment takes into account mental, physical, and social functionality and different kinds of learning materials, media, and technological solutions as parts of them. The quality of video and audio are important factors as a part of media, the option for taking into use multiple channels (video camera pictures) at the same time and transmitting distance learning in a technologically easy way. Teacher's and student's telepresence should be as good as possible and the environment should make it possible to realise interaction between teacher and student easily. Using available fast ATM-network connections and real time video links, learning environments are considered from different transmitting environments , such as

- teacher's workstation
- traditional classroom
- lecture room
- seminar room
- distance learning studio

to different reception environments, such as

- classroom
- lecture/exercise/seminar room
- computer classroom
- single workstation/computer

Student's learning environment may be situated at home or in a library as well. On of the aims of the project is to make studying as far as possible independent of time and place by creating various functional learning environments.

2.1.2 Hypermedia-Based Learning Material

Computers can be used in many ways to support learning in multimedia-based learning environments. In addition to real time videoconferencing hypermedia-based learning material can be used in a computer. With the hypertext's linking properties words/files/formulas/pictures can be linked with the text. The basis of linking that supports studying is the determination of the document's structure. [see Pohjolainen, Multisilta, Antchev.]

The structure of the hypermedia documents is designed on the basis of SGML/HTML. Text is divided into structural parts and linking that supports studying is designed. During the project the necessary software will be produced, with which learning materials can be converted to be suitable for network. Also it will be designed how videos, graphics and animation will be attached to the text-based material. And, in special, it will be studied how the existing video servers can be joined to hypermedia learning environment.

2.1.3 Information Systems and User Interface

Management routines of the studies will be connected to multimedia environment. Via the network students can

- receive information about their studies and enrol for their courses
- communicate with other students and the teachers and get feedback
- take examinations (in the future)

Multimedia-based distance learning, teacher's and student's telematic interaction and hypermedia courseware will be connected in a pedagogically appropriate manner to a learning environment.

2.2 Distance Learning Experiments

The purpose of the distance learning experiments is to test both the technical and pedagogical functionality of the distance learning solutions developed.

The Digital Media Institute at Tampere University of Technology has a fast network connection (ATM) to Kaukajärvi school [see Koskelainen et al. 1996a, 1996b] and to some other educational institutions and to the student dormitory of Student Housing Foundation in Tampere. This environment is used for ATM-based distance learning via multimedia networks. In Kaukajärvi school the first teaching experiments using ATM-connections during spring 1996 have already been made [see Ruokamo-Saari 1996a, 1996b] and in autumn a teaching experiment in Russian language has started [see Puuskari & Suvanto]. Experimental university level teaching between Tampere University of Technology and University of Jyväskylä using fast ATM-based network will begin in the spring 1997.

Adult education will be arranged via open universities that already are familiar with adult education. The contents of adult education are e.g.: mathematics, communications, education, languages. Network solutions are based on Internet, for which student services and counselling that supports interactive private study, is being designed as a part of the project.

Adult education is also arranged as internal education of enterprises. In this project an experiment is carried out with NOKIA/NTC. The purpose is to provide hypermedia based studying material for company's new employees.

3 Preliminary Measures and the Organisation the Project

In the beginning of the project in spring 1996 the following adjustments and mappings have been made:

- Preliminary selections of learning materials and contents has been done taking into account the available teaching experiments in the near future.
- The general structure of hypermedia learning materials has been outlined as well as the possible problems in its production. The media and video servers' potential utilisation has been considered.
- Technical mapping of distance learning has been done.
- Mapping of the interests of the enterprises has been done.

The general plan was prepared in a brainstorming session on 21 May, 1996. In that session there were over 50 participants interested in the field. The results of the session were presented in a multimedia seminar, held later in spring, and the plan was focused on 6th of July at the meeting of the management group.

The organisation of the Distance Learning in Multimedia-Networks project is presented in Figure 1. A management group and supporting group of the project's management has been chosen. ***The supporting group*** is composed of persons from research units that are responsible for the project. ***The research teams*** are divided into three: ***1. Network and technical experimentation, 2. Hypermedia material production*** and ***3. Methods of distance learning*** teams. The research teams consist of researchers on the project. The ***pilots*** participants are both project' researchers and representatives of enterprises and educational institutions. The pilots are divided into the following groups: 1. Fast networks and technical experiments, 2. Natural sciences, 3. Languages, 4. Education, 5. Communication and 6. Enterprise education.

Figure 1. The organisation of the Distance Learning in Multimedia-Networks project

4 Conclusions

In this paper a national Finnish project on open and distance learning has been presented. The major goal of the project: the design of an open learning environment from both the technical and pedagogic points of view, as well as the various distance learning experiments that has been put into practice in order to obtain feedback from the various solutions, have been discussed.

Abstract: Children watch lots of TV and movies, but they rarely make films. This is because the production process is complex, the result is hard to visualize, and one must use and integrate textual, audio, graphic, and video media. Computer-based multimedia facilitates idea development and visualization, and affords the integrated handling of multiple media, so it should aid movie creation and production.

This paper reports on the use of our Movie Authoring and Design (MAD) multimedia system in a summer camp. We wanted to test if this system and the process of motion picture creation could be quickly learned and effectively used by school children. MAD and a control condition of conventional digital editing tools proved to be useful for and usable by eight groups of 3 seventh graders to achieve proficiency and make 2 movies each in the space of a week. The paper presents both quantitative and qualitative data illuminating the children's accomplishments, effects of learning new skills and acquired experience, software and counselor effects, and factors contributing to the success of a novice movie.

Keywords: Multimedia, filmmaking, children making movies, educational software, collaborative learning, empirical studies, qualitative methods, within-subjects experiment.

INTRODUCTION

Children today spend significantly more time watching TV and movies than they do reading. Yet students are not learning to express themselves in the dominant media:

> "The essential medium of expression in the classrooms is no longer print. It's a hybrid of print, video, audio and video games, but unless we provide access to the tools to compose in this medium, we will be training students to be readers but not writers. And if all they do is read these multimedia texts, not only will they have sore eyes, they will be missing out on an important part of what it means to be literate." [Reilly 96]

There is very little literature (but see [Buckingham 90; Paley 95]) describing studies of children creating media. An exception is Reilly [Reilly 94, 96], who documents innovative uses of multimedia authoring at several California high schools as a part of the Apple Classrooms of Tomorrow program. The students create video essays, music videos, and public service announcements, using conventional text editing software and video editing equipment.

Our Movie Authoring and Design (MAD) system [Baecker et al. 96; Baecker et al. 97; Cohen et al. 96, Friedlander et al. 96; Posner et al. 96; Rosenthal and Baecker 94; Rosenthal 95] was designed to assist hierarchical development and organization of movie ideas and components — scripts, pictures, audio, and video, to support their manipulation in a unified manner that is easy to learn and use, and to aid visualization of the ultimate result. It can therefore assist both experienced and novice movie makers, and has been successfully used by children as young as 11 years old.

We believe, as does Reilly, that children benefit by being able to express their ideas in movies, and that digital media can provide rapid learning opportunities and access to filmmaking tools previously reserved for experts. We wanted to study and test these hypotheses in a controlled but realistic setting. We also believe that the idea development, organizational structuring, and visualization capabilities of MAD provides benefits above and beyond those present in conventional consumer digital video editing. We therefore decided to study children's usage of MAD compared to "conventional" digital editing software.

Our report begins with a description of the capabilities and uses of MAD. We then describe the study setting, hypotheses, and experimental method and data sources. A summary of results presents effects of group work, acquisition of new skills, movie quality, effects of software and counselors, and determinants of success. A more complete discussion of the results may be found the companion paper included in the CD ROM [Posner et al. 96, 97].

SOFTWARE FOR MOVIE AUTHORING

MAD is the first system that allows the design and management of words, images, sounds, and video for visualization during the pre-production and production phases of a motion picture. Key design goals were:

- *Hierarchic idea structuring* — the ability to develop movie ideas both top-down and bottom-up, to modify the structure with ease as new ideas arise, and to work at whatever level of detail is desired.
- *Multimedia support* — the integrated handling of scripts [Figure. 1], dialogue or narration, music, sound effects, storyboards, and video shots, and of commentaries on these elements, all tied to the hierarchic film structure.
- *Visualization* — the inclusion of aids to visualizing the film, as for example being able to request a real-time preview of the movie or an approximation to it at any stage in the film development process.

MAD differs from other pre-production filmmaking tools such as script writing software by including multimedia support and visualization capabilities. It differs from other multimedia authoring tools in providing stronger support for film narrative and dialogue structure [Baecker et al. 96].

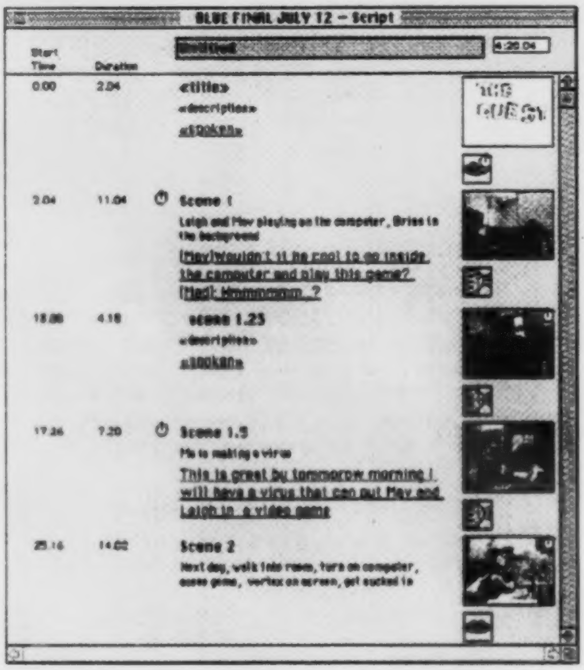

Figure 1: MAD's script view. Timing information is in the left column. The central area displays script details — scenes and shots, director's notes, narration and dialogue. The right column indicates the video and audio components of the movie, as well as annotations. This example is from the movie *Quest* produced at our camp.

MAD is a versatile tool that can be used for many different purposes including:

- Sketching, designing, thinking about, blueprinting, authoring motion pictures
- Developing, presenting, and selling film, video, advertising, and multimedia concepts
- Brainstorming, planning, structuring, and executing lecture-demonstrations and multimedia presentations
- Kids making films; Teaching filmmaking to novices; novices learning filmmaking
- Facilitating reflection on and dialogue about classroom practices by students and teachers [Cohen et al. 96]
- Multimedia messaging over the Internet.

THE STUDY AND THE HYPOTHESES

Our work is a study of filmmaking using multimedia tools in a multimedia summer camp for 7th graders. As movie production is typically collaborative [Gidney et al. 94], we divided campers into groups so that they could share ideas and the work. We used high school students as counselors and technical support staff to provide guidance and technical support. In our pilot pre-camp we discovered that children could complete a movie with MAD or with the control software in under two days. This allowed us to design a within-subjects study in which each group would make one movie with MAD and another one with the control software.

We hypothesized that children would learn quickly to make movies using digital filmmaking software. In particular, we hypothesized that MAD would prove to be both useful and usable for this task.

BEST COPY AVAILABLE

With respect to conventional consumer digital editing software, we felt that filmmakers using MAD could work faster and would experiment with more variations of their movies. Because using MAD should allow authors to focus on the high level structure of their movies at all stages of the creative process, we believed that this should lead to better movies. Finally, we hypothesized that users should have positive attitudes towards the software and show preferences for MAD over the conventional consumer digital movie editing software.

METHOD

Hardware and Software

The Multimedia Summer Camp was run at a new multimedia laboratory at the University of Toronto Schools (UTS), a school known for excellence. The lab was equipped with networked personal computers and camcorders.

The experimental software was MAD 2.4 running on Macintoshes with system 7.5 and Quicktime 2.0. For the control condition, we attempted to simulate "conventional video editing" with two VCRs by using software [QuickMooV 95], which provides minimal functionality of selection, cutting, and pasting of digitized video segments. Both software conditions had to digitize their analog video from the camcorders to the computers, using Apple Video Player [Apple 95], and to compress large video files, to maximize usable disk space.

Participants

Counselors and support staff consisted of six high school students. The four counselors were 2 males and 2 females, 2 grade 11 and 2 grade 13 students. The technical support staff were male grade 11 students with extensive computer experience. All staff went through a pre-camp, where they were able to use the software to make their own movies, and then to supervise groups of campers, grade 7 students from their own school, to give them experience with this type of counseling.

The campers were 24 grade 7 students who were selected randomly from 230 applicants, 9 females and 15 males (one female was unable to attend due to illness). All applicants were 12 and 13 year old students from a suburban Toronto school district. Their computer experience varied from no experience at all to 9 years of computer usage.

Camp Process

The camp was run for two weeks. Twelve campers attended each week — 5.5 hours per day for 5 days. The campers were divided into four groups; we controlled for computer experience and gender, and tried to ensure that group members were from different schools.

Each group was assigned a counselor and a software condition for making their first movie, which was to be a movie about themselves. All groups were given a brief talk about moviemaking and a demo of the software. They were then allowed to work on their movies at their own pace under the guidance of their counselor. The groups spent between 5 and 9 hours working on their first movies.

After the completion of the first movie, there was a showing of all films, followed with a lecture by a professional movie maker on various aspects of his work. This talk included a discussion of some of the problems that were encountered in the first movies — bad sound quality, unimaginative camera work, sloppy editing.

Next, our original groups of campers were assigned a new counselor and new software for making their second film, on a topic of their own choice. Another demonstration of the new software was conducted. The groups spent between 5 and 11 hours working on their second movies. On the last day of camp there was an awards ceremony with prizes. Every camper could take home a VHS copy of their work to show family and friends.

We also included Internet surfing and computer games to enliven and enrich the campers' breaks.

DATA COLLECTION AND MEASURES

We collected large amounts of data using questionnaires, audio and video journals, digital records, paper artifacts, and group discussions.

Expertise and Accomplishments: A background questionnaire asked about campers' experience with technology (e.g., video games, VCRs, video cameras), computers, moviemaking, other interests, and group work experience. The campers' knowledge of moviemaking was also assessed three times throughout the camp [Posner et al. 96].

After each movie, the campers filled out a questionnaire asking about their experiences with the software and with their group. Post-movie group discussions also addressed campers' experiences and concerns.

Movie Structure: We collected and preserved their paper artifacts including rough notes of brainstorming ideas, storyboards, and scripts. We gathered the original footage filmed by the campers and kept VHS copies of all final films for evaluation and analysis.

All digital records and files were saved (approximately 600Mb/movie); these included scripts, digitized video segments, and versions of the evolving movies. We also analyzed movie and script structure using a detailed quantitative evaluation form [Posner et al. 96].

Movie Quality: The quality of the movies was rated by three "experts" — one movie maker and two avid movie viewers. They used three categories (technical merit, creative ideas, and overall impression) and a five point scale (excellent, very good, good, fair, poor). We used the sum of the ratings of the three experts as the score in each category; for example, the overall scores for the sixteen movies ranged from 3 to 15. The sum of the three categories produced a total score ranging from 12 to 44 (out of 45).

Process: For recording the moviemaking process, the counselors kept records of their groups' work using paper activity calendars and audio journals. We also collected video journals that contain the first two hours of work on each movie, six of which have been analyzed for this paper.

To visualize the process information we plotted the groups' activities by combining details from calendars, audio journal transcripts, observers' notes, and digital time stamps on files according to the following categories: brainstorming, script writing, filming, digitizing and compressing, editing, Internet searching, and miscellaneous.

Preferences: The two post-movie questionnaires asked about the ease of use and enjoyment of the experience with the software. A final questionnaire asked campers to rate and compare the two programs in terms of overall preference and in terms of specific moviemaking activities.

SUMMARY OF RESULTS

This section provides a brief summary of the study results obtained using quantitative and qualitative analysis of data collected of the students' digital filmmaking activities. For a more complete discussion of these results see the accompanying ED-Media/Telemedia '97 CD ROM.

Group Work: Campers learned how to work in a group sharing responsibilities by dividing the moviemaking roles such as writing, directing, acting, and camera work. Some groups rotated campers through the various roles, while others allowed individuals' preferences and strengths to guide the role selection.

Learning Moviemaking: Children's filmmaking imagination and creativity is quite extraordinary, allowing them quick entry into the world of film authorship despite the lack of filmmaking theory, technical skills, or computer background. The highest rated movie with a perfect score of 15 was *Quest* a story about kids being sucked into a video game. The group started with a very detailed MAD script (283 words) outlining their intricate plot and dialogue. Both live action and video games were used, as well as smooth creative transitions in which game characters fade in and out of reality. The soundtrack combined the *Mission Impossible* theme song imported off the Internet, computer game sounds, and audio recordings input via the camcorder or directly into the computer. This 4.3 minute long film contains 41 shots (camp average was 15 shots per movie) and took about 10 hours to complete (average completion time was 7.5 hours).

Learning New Technology: The campers quickly achieved competence in many different and new technologies — Macintosh computers, video cameras, digital editing, digitizing, and specific software.

Instructor: "How was it using that software?"
Camper: "It was the first time for me. I found it pretty good."
Instructor: "Easy, hard?"
Camper: "Kinda hard, but then you catch on and it's easy."

Learning Organization Techniques: Organization skills are extremely important in moviemaking. Some groups improved significantly over time. For example, on their first movie one group spent minimal time scripting and planning. They filmed without rehearsal and without retakes, edited quickly and then moved on to the next part of the movie. The same group was much more professional on their second movie. They spent much time discussing the plot and resolving the details of their story. Point-form notes were expanded into a list of scenes and then into a storyboard depicting 10 scenes. Although the dialogue was not written on paper, the participants improvised and rehearsed their lines, and recorded numerous takes of each scene. They recognized the payoffs from this improved work organization — planning story details, creating a storyboard, filming ordered by location, digitizing in related segments, and editing in one stretch:

Camper : "Acting we did together, then we edited. We did it different from last time when we did a little bit of acting and a little bit of editing. This time we did all the acting together. I like it better with all the acting first because it is easier. "

Movie Quality: The increased experience and exposure to filmmaking concepts resulted in children's second films being more complex technically than their first films (Movie 1 = 6.3, sd = 2.38, Movie 2 = 9.6, sd =2.56) ($\underline{F} = 7.84$, df = 1, 15; $p < .05$). The second films were also judged to be of significantly higher quality (Movie 1 = 6.3, sd = 2.7, Movie 2 = 9.9, sd = 2.9) ($\underline{F} = 7.15$, df = 1, 15; $p < .05$). The children spent more total time working on their second movies than on their first (Movie 1 = 287 min, sd = 56.9, Movie 2 = 364, sd = 64.5) ($\underline{F} = 9.9$, df = 1, 15; $p < .05$) and also did more editing and refining for their second films. .

Software Effects: MAD proved to be both useful and usable, confirming previous studies [Baecker et al. 96]. Software condition did not effect movie quality, however, working with MAD seemed to encourages more editing and refining than working with the control software. Children preferred MAD to the control software; 91% preferred MAD and 9% had no preference. Given a choice of software, the campers would prefer to take MAD home:

> Instructor: "If you had a choice, which one would you take home?"
> Camper 1: "MAD."
> Camper 2: "MAD, because it's better, just better."
> Camper 1: "MAD has more options."
> Camper 3: "You can do more things in MAD."

Counselor Effects: Despite our attempts to balance the influencing factors, counselors had significant effects on group work and movie quality. Counselors contributions to their group's efforts varied from minimal input to extremely controlling influence:

> "Press shift, drag the button, go back, let go ... get rid of this and this too ... fast forward to ..."

The counselors' feedback approaches ranged from excessively positive to constructively critical feedback. Prior experience and attitude of counselor also effected the groups' experience in either a negative direction,

> "We're going to start making the movie. Its going to be a bit tedious ... filming, then editing on the computer."

or in a positive direction,

> "We're going to be using different software. ... Its much better. You can do lots more with it, like include Internet pictures and soundtracks."

The overall movie scores were also related to counselors ($\underline{F} = 4.7$, df = 3, 15; $p < .05$).

Determinants of Success: We looked at the most successful films to see if there were common elements among these movies and among the work processes followed by these groups. Five out of sixteen films scored more than 30 points (out of total 45). The groups working on these top films spent significantly more time in the idea generation and script writing phase (top 5 films = 1.7 hours, other films = 0.8 hours, $t(14)= 3.65$, $p<.001$). The movie quality scores were significantly correlated with the time spent in the idea phase ($r^2=.54$, $p<=.01$). Although there was no significant difference in final movie length, the top five movies had significantly longer scripts (257 words compared to 134 words, $t(14)=2.88$, $p<.05$). And although there was no significant difference in number of scenes, these groups produced more detailed storyboards (4 scenes compared to 1.6 scenes).

Another similarity that was observed among the top five movies is the amount of critical reflection undertaken by these groups. The guest moviemaker suggested that everything in a movie must be done for a reason, every camera angle and motion, every scene change. These groups seemed to follow this advice, they spending much time discussing the details of their movies. Their films seemed better planned, thought out, and more intentional decisions were made than on some of the lower rated films. Their enhanced shared understanding, using scripts and storyboards, and critical evaluation throughout the moviemaking process lead to films of higher quality.

CONCLUSIONS

Our multimedia camp was a success, a worthwhile and rewarding undertaking for 23 seventh graders. All groups successfully completed two movies; campers were proud of their movies and eager to take them home to show to family and friends. Many campers and their parents wanted to know if they could attend our camp again, next year. If this were possible, it would be interesting to see what they could accomplish one year later.

Yet we must temper our enthusiasm with the reality that multimedia camps are very hard to run. Equipment is still expensive and rare in local schools. Significant numbers of video cameras, computers and experienced support personnel are required for smooth function. Technical problems often lead to lost work and frustration with software and hardware.

Discussion and Implications

Given the lack of literature in this area, other thorough studies of moviemaking need to be done. In our next in-depth study of the use of digital filmmaking technology, we would like to change the task duration and the training and support given to the students.

The staff and counselors' background and expertise in filmmaking, hardware, and software had a dramatic effect on the campers' experience. Small amounts of well-timed instruction in the lecture about filmmaking held after the children finished their first movie produced immediate effects, such as an improved variety of camera angles, better sound, and better editing. Although the fact that a relatively inexperienced staff can run such a camp successfully is encouraging in terms of the ability to replicate such as program widely, we are convinced that having a more experienced and better trained staff would have produced a richer learning experience for the campers. To paraphrase [Reilly 96], the teacher has the primary role in the classroom and the technology has the secondary role.

More specifically, it was the case that without close guidance and highly structured instruction, children did not naturally follow the iterative design process and critical appraisal of their movies. We wanted students to go beyond the basic use of the tool to a more sophisticated discipline which involves the careful crafting of various media representations such as script or storyboard, which may involve collaborative work by multiple contributors bringing different skills to the endeavor, and which must involve thoughtful critiquing and iteration upon the result in order to produce the best possible product. This did not happen in our camp as much as we had hoped for.

Rather than trying to do this in a summer camp, it is more important to integrate collaborative multimedia authoring into the school curriculum as a vehicle for expanding students' creativity with projects and assignments in courses such as history and science. This should be done with close supervision and with continual and critical feedback from both teacher and classmates [Reilly 96].

If we can achieve this, we believe that tools such as MAD supported with reasonably straightforward learning materials can enable a powerful and compelling new classroom literacy for telling stories, exploring concepts, and expressing ideas.

ACKNOWLEDGMENTS

We are grateful to the MAD developers Alan Rosenthal, Eric Smith, and Vanessa Williams for tireless creation and support of an excellent prototype; Isabel Jevans for invaluable assistance with design of the study, running of the camp, comments on these drafts; Alexandra Mazalek for excellent technical and creative assistance during camp; Steve Poplar for organizing the camp and allowing us to use it as a basis for our study; University of Toronto Schools for providing equipment, facilities, and the support of their students — Adrienne, Mike, Prashant, Rosanna, Dennis, and Sebastian; Jason Chang for helping during the camp and with data coding; Andrew Cohen for helping design this study; the campers from the Scarborough Board of Education; and to the CulTech Collaborative Research Centre, the Natural Sciences and Engineering Research Council of Canada, the Information Technology Research Centre of Ontario, and the Networks of Centres of Excellence on Telelearning of Canada for financial support.

Reducing Distances for Face-to-Face Education

Nelson De Luca Pretto
Federal University of Bahia/Brazil - Faculty of Education
E.Mail: pretto@ufba.br
Home-page://www.ufba.br/~pretto

Abstract: The purpose of this paper is to question the necessity of national programs of distance education in Brazil without considering the reality of the states, with particular reference to Bahia.

The Brazil government has actively promoted distance education projects not always taking into account the local reality and the public higher education system.

Bahia has five public universities spread throughout the state, already working together with many public primary and secondary schools. We are discussing the possibility of linking all sectors of public education, using new technologies of communication, and collectively developing programs to re-design the focus of training courses, undergraduate courses and support public schools and teachers.

Our goal is to create a new pedagogical vision, supported by these new technologies, which, by their very nature, reduce distances, in conjunction with face-to-face education, to transform schools into a place where culture and knowledge are produced and promoted.

Do we really need distance education?

The development of new communication and information technologies is occurring at an overwhelming pace. I use the term communication to refer to mass-media systems such as TV and cable networks, as they are currently structured. The term information refers to computer-based technologies such as Internet, Intranet and on-line services, etc.

All over the world there has been a merging of several once divergent fields, which, until recently, had even been competitors, such as communication, information and entertainment corporations. The English publication *ScreenDigest* shows us an intersting map of this converging media landscape in its Jannaury 1994 issue [ScreenDigest, 1994].

Today's electronic equipment is becoming obsolete very quickly and once separate devices are converging because of the rapid evolution of technology [Gilder, 1996]. According to *ScreenDigest*, since 1992, multimedia "is coming to signify a specific convergent concept in which single carriers deliver a complete audio-visual range" [ScreenDigest, 1994].

Distances shrink due to the myriad of possibilities for communication. In Brazil, academics are discussing whether in fact we are taking full advantage of this world of information, while keeping in mind the great social disparities that exist in our country and in other developing countries.

897

According to the 1995 National Household Survey (PNAD - Programa Nacional de Amostragem Domiciliar) carried out by the Brazilian Institute of Geography and Statistics (IBGE) [1], 78% of Brazilian households have televisions, which makes the programming of the large national networks accessible. The most important broadcasting system, whose signals can be tuned in in 99% of Brazilian municipalities, is *Rede Globo*, controlled by the Roberto Marinho family. They control, according to the *Folha de São Paulo*, 60% of the advertising market through their 17 TV stations and associated TV channels. Recently, Rede Globo established an association with the Murdoch Group, thus making it the fifth largest communications conglomerate in the world and they are beginning to operate the DBS TV system in Latin America.

However, this is only one-way communication. True communication requires interactivity with information flowing in two or more directions. The same IBGE survey showed that only 22% of Brazilian households have a telephone line, which is a basic requirement for access to the Internet.

In Brazil, the policies of the current federal administration have been detrimental to public universities by cutting budgets and reducing staff. They have even proposed revoking the policy of free public education which has been in effect since the system was established. The Brazilian public university system is vast and covers the major population centers of all 27 Brazilian states. In the last few years an increase in the number and size of private universities has changed the face of higher education in Brazil.

The new proposal also includes a controversial subject: university autonomy. Represented as an important advantage of a new "democratic" system, the type of autonomy proposed is considered by some within the university as a trap, because outside large urban centers, São Paulo and Rio de Janeiro, the public universities and most individual faculties are not and will never be economically viable.

On the other hand, Brazil is going through difficult times with respect to its institutions of higher education. One can infer from its contradictory movements, pronouncements and projects that the government is putting into practice a plan to suffocate these institutions and is using distance education as possible solution for at least a few of the problems in primary and secondary schools. This discussion, while not a priority subject in Brazilian society as a whole, is going on inside the universities in a very intense manner, due mainly to the government's proposals regarding university autonomy. I do not think it is possible to overcome the backwardness of the educational system without a successful partnership between the public institutions of higher education and the public primary and secondary educational system.

We are experiencing what may be described as a generalized *fever* of distance education projects in an attempt to solve education problems as if it were possible to develop these projects without taking into account all aspects of this complex system.

It is precisely this government, which is providing, in theory, incentives to distance education projects, including the creation of a department specifically for the subject (Secretariat of Distance Education), that has clearly stated its position against maintaining the present public higher education system. This policy, in my opinion, presents an inherent contradiction. In this paper, I intend to discuss and analyse the relationship between distance and face-to-face education with particular reference to current situation in Bahia/Brazil and to illustrate this contradiction.

Distance Education in Brazil: a Quick Overview

In Brazil, there have been numerous initiatives to develop distance education projects. Parallel to the developments in the private sector, since the 1960s, by providing in particular technical courses for specialized training (e.g. the pioneering *Brazilian Universal Institute*) there have been other significant governmental movements in this field worthy of mention.

One of the pioneers in Brazil, the *Saci Project* was implemented experimentally in the State of Rio Grande do Norte in northeastern Brazil at the end of the 1960s without achieving significant results, as Laymert Garcia dos Santos described in his book *Desregulagens* [Santos, 1981]. Other experiments in the field were or are being developed in Brazil, as is the case of the regular courses offered by the Educational TVs of the states of

---

[1] see URL: http://www.ibge.gov.br/

Maranhão, Ceará and Amazonas (northeastern and northern Brazil), to meet the needs of the last three grades of primary school [2].

According to Lobo and Leobons [Lobo, 1988] there have been innumerable distance education initiatives dealing with supplementary education and teaching by correspondence. In 1971 the Brazilian Educational Technology Association (ABT) was created. Since 1972, it has maintained advanced training courses for Primary School Certification and published a periodical, *Tecnologia Educacional*, thereby providing a forum for discussion on the topic. As Ligia Leite explains, both the Association and the periodical have undergone name-changes reflecting the evolution of the concept of the relationship between education and communication technologies [Leite, 1992].

The National Institute for Educational Studies and Research (INEP) published a State-of-the-Art report on the matter in 1987 (Bibliografia Especializada em Educação - Educação à Distância), as part of the Latin-American Information and Documentation Network - REDUC, which brings together 23 educational research centers in 17 countries in Latin America and the Caribbean [MEC, 1987].

As stated previously [Pretto, 1996], in 1986, the Education Ministry tried to breathe new life into the *Saci Project* based on the work of an Inter-Ministerial Commission, officially established pursuant to charter n° 390/86, involving both the Education and Communications Ministries, with the aim of studying the "possibility of implementing a basic education system via satellite". The team from the Communications Ministry showed a great deal of interest in providing incentives to use the Brazilian geostationary satellite for educational purposes. What was not clear, however, was pedagogical project which would be the cornerstone of this initiative. The very group that chartered the commission was already showing signs that it was looking to implement a *parallel* educational system with classes being transmitted from Brasília (or Rio de Janeiro) to the rest of Brazil and which would be captured by nearly 30 thousand satellite dishes to be installed in the different Brazilian municipalities [Pretto, 1996]. This meddling by other ministries in education is no novelty. According to Maria Luiza Belloni, this had already occurred when the *Saci Project* was negotiated, when the Education Minister (1970/1974) evidently became irritated with the director of INPE who "invaded without ceremony the dominion reserved for the Ministry of Education and Culture"[Belloni, 1983, p. 176].

When the Commission's work was finished, a generic report was published without any concrete decision on the use of the satellite for educational purposes. Nine years later, the Education Ministry launched its *TV-School project*, also centered on the use of satellites and satellite dishes in the schools, this time to train primary school teachers. Numerous articles are being written or have already been published on the subject and no further detail is necessary here.

This collection of experiences and experiments in the field of distance education has made us reflect more deeply on the need to evaluate the information that is already available while at the same time seeking to introduce new resources in communication and information technology into the day to day lives of our *traditional* face-to-face schools. This reflexion has been built into a current project the goal of which is the transformation of public education in Bahia.

The transformation of public education in Bahia

I cannot deny the importance of these national distance education projects and programs. Nevertheless, I believe it is necessary to analyze the need for and the size of these types of projects, taking into account the context of each and every Brazilian state. In order to overcome the above-mentioned contradiction, we will reflect upon the feasibility of simultaneously strengthening public learning institutions at all levels as well as promoting greater interaction among them.

In Bahia we have been pondering this issue a great deal since the current situation here leads us, *a priori*, to think that we do not need distance education programs to the degree nor with all the characteristics of other projects that are being implemented in Brazil. With this situation and the current conditions in Bahia in mind, we are analyzing - evidently with many internal conflicts - the real need to implement distance education programs

without first considering our reality. In particular, we should analyse the presence of public universities in the state as a whole. There are five public universities, spread over 21 *campi*, covering a good portion of Bahian territory.

Within this context, it is important to reflect a little upon the need to establish as a priority a closer relationship between theoretical analyses - produced inside the universities - and the day-to-day life of our primary and secondary schools, giving special emphasis to those professionals who, already in active service, need to be adequately qualified to carry out their activities. Especially if we are referring to the great number of teachers who, without adequate nor appropriate training, work almost heroically in primary and secondary schools, without the minimum academic qualifications to fulfill their roles as education professionals.

The public schools have been abandoned, the teachers are unprepared and are appealing for support. Public universities - good or bad - however, are present in practically all the state. These universities, while also carrying out their activities - under absolutely precarious conditions - are also working with the public education system in each of the regions where they are located.

I believe it is important at this historical moment to use new technologies, that *shrink* distances and bring lecturers, teachers and students from these universities and schools together, to foster group action and build a closer relationship between the public university, secondary and primary school systems.

This combined institutional effort is to support each school, in each region, in the development of a collective process to provide teachers working in the classroom with the necessary academic qualifications and keep them up-to-date.

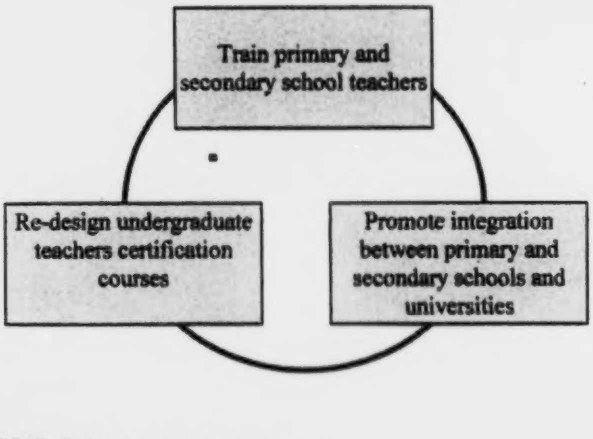
To develop this project it is necessary to examine existing programs and projects, to introduce the new resources in information and communication technologies, to re-direct them collectively in an attempt to diminish the distances that separate the different universities and, principally, the universities and the public education system (primary and secondary schools).

When thinking about *reducing distances*, our aim is not merely to increase the number of people who have access to education via TV broadcasting. The use of these technological resources is fundamental given that they are not only new technologies - forced on us by the electronics industries - but that they are the elements that are structuring a new language, whose form and internal logic are determined by a secret alliance between electronics and the human spirit [Babin, 1993].

Given this perspective, steps should not be taken to create not only *curricula* and didactic programs and materials in a centralized manner to *flood* the school with information, but also, and more importantly, develop a critical awareness.

Therefore, when designing programs to train or develop teachers acting in conjunction with education ministries (federal, state and municipal), universities and public schools taking into account on-going projects at nearby universities, we are promoting a new practice, based on *three basic interdependent elements* [Fig.1].

Figl: Three basic interdependent elements for reducing distances in education projects



Train primary and secondary school teachers
Re-design undergraduate teachers certification courses
Promote integration between primary and secondary schools and universities

BEST COPY AVAILABLE

These ***interdependent elements*** are considered ***the minimum requirements*** for the development of the project. Our aim is not simply to develop current training, advanced training and certification programs for teachers, now *at a distance*, using different media. This is no guarantee of new and improved training methods for these teachers. Nor do we simply want to develop current certification programs - or part of them - at the distance, with the *simple* objective of "increasing the number of graduates".

On the contrary, we believe that new technological resources, which make it possible to *take actions at a distance in* ***conjunction*** *with those taken face-to-face*, constitute the *structuring* elements of a new pedagogical vision. This is because, these resources constitute the elements of a new vision of the production of knowledge on the planet on the dawn of a new millennium.

We live in a mass media society and schools need to be equipped and ready to prepare future generations to know how to take advantage of all information available thus transforming schools into a place where people are able to collectively produce culture and knowledge. A new school will be born, with new teachers, working face-to-face with their students supported by these new tecnhological resources.

Abstract: Although Internet technology and the WWW have been hailed as a panacea for education, and distance education in particular, few people are making effective use of the technology or demonstrating scaleable examples, especially in terms of replacing face-to-face teaching. The Open University (UK) is one of the most successful distance teaching universities in the world and this paper presents some of the models attempted and lessons learned from large-scale Internet teaching on computing courses.

Introduction

The World Wide Web has been heralded by the popular press [Reinhardt 1995] as a panacea for education, and for distance education in particular. Suddenly, many conventional universities have started to offer Internet, distance-taught courses constructed from conventional lecture notes translated into HTML with a few hyperlinks. But what about *teaching*? Although such material may be a useful supplement to students studying conventionally, the demands of distance teaching extend far beyond provision of conventional course materials [Mason and Kaye 1989], and the challenges of *effective* remote education concern the quality of a student's experience. Even at a distance, students' interactions with their teachers and with other students give them perspective, place them within a community of learning, and contribute to their mastery of concepts and skills.

Face-to-face teaching and practical sessions (hereafter called 'tutorials') are seen as a focal point in distance teaching, where concepts become immediate and personal through students' interactions with both their teachers and each other. The Open University's early experiences with electronic presentation of courses have highlighted both the importance of face-to-face tutorials in distance teaching, and the challenge of replacing face-to-face tutorials with effective electronic substitutes. Providing effective tutorials outside the constraints of a given room and time has relevance beyond established distance teaching. It is part of the growing need for flexible delivery demanded: *by multi-campus universities*; in disciplines (like Medicine) in which *expert teaching staff is scarce*; in cases where *particular expertise (e.g. technological knowledge) is concentrated in one location*. This flexibility can reduce constraints on instructors as well as students.

In translating the tutorial for Internet presentation, the priority is to preserve the immediacy of the face-to-face tutorial, despite the problems of cost, compatibility and synchronisation that apply. This paper reports experiences of 'electronic tutorials' conducted over two years as part of on-going trials presenting Computing courses via the Internet to students world-wide. It describes the university context, the technology strategy, and the synchronous and asynchronous interaction models used, and it discusses the issues observed during these trials.

Background: the Open University context

Over 26 years, the Open University (OU) has developed a well-tuned machine for providing high-quality university education for part-time students studying at a distance. With more than 150,000 students per year and over 120,000 degree graduates to date, it is one of the most successful distance teaching universities in the world. All OU undergraduate teaching is through 'supported open distance learning'. The teaching and support network for students manifests itself in five distinct aspects: *teaching materials; tutorial support and assessment; counselling support; examinations* and *enquiry services*. Each student studies at home using teaching material delivered primarily by mail but using a variety of media (custom-designed books, CD-ROMs, audio tapes, video on tapes or UK-television broadcasts, laboratory materials). All teaching material is specifically designed for students working independently. This teaching is *supported* because all students are assigned a local instructor, who answers course-related questions throughout the year via telephone conversation or written correspondence, or during one of the regularly scheduled face-to-face tutorials when the students and instructor meet at in a conventional classroom setting for 1-2 hours. Throughout the course, the student is required to submit written assignments which the instructor grades and annotates, providing essential feedback.

The challenges for a large, distance teaching university include: scale; a commitment to access, despite hugely varying student circumstances; rigorous quality control which must be completed before courses are presented; and rapid feedback to a dispersed student population.

Scale: With over 300 courses offered in a variety of undergraduate and post-graduate degree programs, and with as many as 8,000 students in some courses, scaling for student numbers requires considerable organisation and efficient administration.

Access: The OU has no barriers to entry: the ethos of the university is to be "open and equal". Removing or minimizing the barriers to study makes 'cost', supply, and other practical considerations crucial in the use of technology. The principle of access also extends to flexibility: over 70% of students are working full-time and studying part-time, so their learning must fit around other responsibilities. In the past, people have studied with the OU from places as diverse as airplanes, cruise ships, oil rigs, or even nuclear submarines. The conventional OU study system copes well for students in these situations, and changes involving electronic communication must not disenfranchise them.

Quality control: Courses are designed by a multi-disciplinary team producing custom text, software, audio cassettes, video for broadcast, and CD-ROMs. All materials must be completed and evaluated in advance; courses undergo rigorous developmental testing with a student cohort before presentation. A pre-eminent commitment to quality teaching demands that technology be made to serve education, rather than teaching chasing technology.

Rapid feedback: Even though 40,000 assignments are processed per week, the students usually receive their marked assignments within a week of the instructor submitting them. Retaining and motivating students hinges on rapid feedback, which makes communication (paper-based or otherwise) a key issue. This has been one of the barriers to the OU teaching outside the UK, where communication systems are often less reliable.

Internet communications strategy

The commitment to access has a profound effect on how courses are designed and what may be required of students; courses may not impose an onerous burden in terms of powerful machines or expensive network access. Although electronic communication has played a part in some OU courses for well over a decade, until recently this has been limited to a small number of courses where electronic communication was a topic in the course, and a few hundred students used one of two proprietary local conferencing systems. For the past three years, the OU has also been adopting a separate Internet-based strategy for world-wide delivery of supported distance learning courses. The university itself is effectively a very large national Internet Service Provider for its students, with local dial-in points throughout most of the UK. Nevertheless, students must pay per-minute charges for local telephone calls, and so Internet access software must provide some method of off-line working to help students minimize call charges. Over 30,000 students will make use of dial-in access to the university in 1997.

Given the current rapid developments in Internet technology, it would be tempting to develop an electronic communication strategy by assuming that students gain fast connection to the Internet via ISDN, or even a direct connection to an MBONE site--such as the one proposed by Watabe and colleagues [Watabe et al. 1995]. However, although it appears to be relatively 'future-proof', allowing advances to be built onto the present system, its current cost is prohibitive for an institution committed to access. This does not mean that the OU cannot use fast network connections to deliver high bandwidth material for teaching. It *does* require a policy of *graceful degradation* so that, as a student's personal computer specification or the speed of connection to the network decreases, the student can still receive a suitable version of the interactive component of the teaching.

The assumed 'least common denominator' in equipment is access to an offline e-mail facility and the ability to decode attached MIME or uuencoded files. No assumption is made about the speed of the student's connection, which could be as low as 1200 baud. But, for the majority of OU students, the minimum hardware specification is an 8-Mb PC running Windows 3.1 with a 14.4 kbaud modem, significant numbers of students now have higher specification machines running Windows 95 and use higher-speed modems to access the OU.

All students are provided with the Netscape browser (supporting some HTML, Java, WWW file uploads, and integrated off-line e-mail), although they may use almost any WWW browser if they prefer. The university provides PPP dial-up points in the UK and POP e-mail for off-line e-mail reading, although students outside the UK are recommended to find their own Internet Service Providers with local e-mail, in order to avoid long distance telephone calls or long waiting times on Internet connections.

The experience reported here is within this Internet-based strategy: the trial presentation of Computing courses via the Internet. The first trial in 1995 involved 29 students in 9 countries studying entry-level Computing with 2 UK instructors. Its successor in 1996 has involved approximately 300 students and 22 instructors on an entry-level course, and 50 students and 2 instructors on an upper-level course, using new electronic tutorial models, improved marking tools, and more sophisticated conferencing. In 1997, over 500 students from all over the world will study a range of courses supported by at least 25 instructors.

Four main communications facilities were employed in the 1996 trial:

i) **E-mail**: Students were provided with clients for off-line mail systems (Eudora and Netscape Mail). They could send message to their instructors, to fellow students, or to groups via a mailing list facility connected by gateway to the web-based conferencing system. Many students and instructors constructed their own special-topic mailing lists. Students were required to check their e-mail regularly.

ii) **Web-based conferencing**: The main asynchronous text-based conferencing system was based on the Hypernews system (http://union.ncsa.uiuc.edu/HyperNews/get/hypernews.html), with some additions to facilitate course organization, and with e-mail gateways so that it could be used to broadcast messages via e-mail as well as the conference. Students who had only e-mail access could post into the conferencing system--into the appropriate thread--by sending to a special e-mail address. Anyone in the conferencing system could elect to receive all postings to any thread or sub-thread as e-mail, so that they needn't check for new messages; hence use of the conferencing system was effectively optional. Instructors used the conferencing system to construct tutorials in HTML and to conduct discussions in their tutorial groups.

iii) **Internet Relay Chat**: Internet Relay Chat (IRC) provided a synchronous text-based discussion facility to all students with the standard equipment described.

iv) **Enhanced CU-SeeMe and RealAudio**: For the audio-graphic tutorials, students in the upper-level course (all with sound capability) were provided with Enhanced CU-SeeMe software (http://goliath.wpine.com/cu-seeme.html), which gave them a slow-scan video image of the instructor, an IRC-like synchronous text chat facility, a shared 'whiteboard', and limited two-way live audio. For better audio quality, students were also provided with RealAudio software (http://www.realaudio.com/).

What do students want from tutorials?

Distance students often report a feeling of isolation when studying because of their lack of contact with an instructor or other students. The emphasis on electronic tutorials arises from previous experiences of electronic presentation, as well as from earlier analyses of what students derive from face-to-face tutorials. The benefit to students is only partly academic; the tutorial is an important social focus that allows students to build relationships with their instructors and other students. Students report that tutorials provide:

i) a chance to meet the instructor who is marking their work;

ii) demonstrations of expert behaviour, worked examples, an alternative look at the course material;

iii) structure; milestones; incentives; an indication of the appropriate emphasis or degree of importance for various topics in the syllabus;

iv) pointers about the kind of problems they will face in assignments;

v) learning from other students' questions, mistakes, insights;

vi) reassurance that the student is making appropriate progress, and that the student's progress is comparable to that of other students;

vii) social contact with other students (Tutorials are crucial in establishing student networks, etc.)

OU statistics over years indicate that students who attend tutorials tend to perform better than those who don't. However, poor or less-confident students tend not to attend tutorials, and nor do busy or remote students or those unable to travel. For students who cannot attend face-to-face sessions, electronic communication can help overcome many of the problems faced by distance learners [Alexander 1992].

What is a typical face-to-face tutorial?

In the broadest characterization, face-to-face tutorials tend to have two main parts:

i) a diagnostic component, in which instructors clarify where students are with respect to coursework and answer any questions, and in which they reflect on a previous assignment, giving attention to points of difficulty;

ii) a lecture or problem-solving component, in which instructors present examples and issues and elicit discussion, or in which students solve and discuss problems.

Instructors are given a 'free hand' in running their tutorials, but the 'typical' tutorials they report fall into three general formats:

i) open question and discussion sessions which are student-centred.

ii) lecture-type sessions which provide an augmented view of the course material, either through additional explanation or worked examples.

iii) workshop-type, problem-solving or practical sessions in which students work individually or in small groups on problems of varying difficulty. Interaction and discussion are emphasised.

Models attempted

At the start of the term, several electronic tutorial models were suggested to the instructors; the suggested models tried to accommodate both the constraints and the opportunities inherent in electronic communication in order to provide valuable tutorial functions with the simplest effective technology--hence the emphasis on structured, asynchronous tutorials. Among the suggested models were the 'asynchronous problem-solving and discussion' model and the 'asynchronous group working' model which appear in Table 1. The instructors adjusted those models and invented new ones to suit their own teaching. Tables 1- 3 present a distillation of those experiences, grouped by mode (asynchronous, mixed, and synchronous) and ordered by the number of examples.

NOTE: Tables 1-3 appear in the electronic version of this paper only

Issues:

duration of tutorials: Preliminary results suggested that deadlines and milestones are important in electronic tutorials, and so early asynchronous tutorials were held over 2-3 days, often a weekend. However, many instructors reported that 2-3 days just wasn't long enough, and that they had more success with the week-long tutorial. The advantages of the longer period include:

- time for students to reflect on or to re-try exercises
- time for busy students to 'look in' (hence better 'catchment')
- the opportunity to tackle problems of realistic size, rather than mini-problems -- partly because the tutorials can be cumulative, and a momentum can be created.

tutorial group size: There is no clear indication of optimum group size. Active participation in the tutorials was low, but a good interaction could be achieved with 3-4 students, and instructors remarked that many students were known to 'lurk'. In general, the pattern of participation appears to have followed the pattern observed in other conferencing studies: 1/3 are active participants; 1/3 are occasional participants; 1/3 lurk when they have time.

instructor teams: Those instructors who were able to collaborate with one or more other instructors seem to have benefitted, both by sharing the load (and thereby giving students better coverage) and by having the contact: instructors appear to get some of the enthusiasm from each other that they miss from face-to-face tutorials. Some of the best reports come from combined-group tutorials.

participation: Participation appeared low, but several instructors remarked that it was comparable to attendance at face-to-face tutorials. Instructors and students both remarked that electronic tutorials reached students unable to attend face-to-face tutorials. 'Attendance' at tutorials tended to drop off, but was revived by alternative tutorial strategies (e.g., role play) and by other mechanisms (e.g., requiring students to register in order to participate).

lurkers: Instructors consider it an advantage that some students can lurk, but lurkers pose a disadvantage for instructors: less feedback. In face-to-face tutoring, there is still some interaction with passive students, and instructors cater for a sort of 'passive absorption'. In electronic tutoring, the lurkers are 'invisible' and the instructor may feel that few students are attending. Many instructors reported that nearly all of the students in their groups read the tutorials, even if they didn't contribute: *"Even those students too shy to join in later said they followed the exchange of emails and said they found it useful."*

interaction: Several instructors reported that they get *more* interaction in their electronic tutorials than in their face-to-face tutorials. However, several instructors reported that they couldn't raise any interaction at all. About interaction, both instructor and student experience are divided -- some successes, some disasters. What evidence we have suggests that including some synchronous device like IRC is likely to increase the satisfaction with interaction: *"I think the IRC experiment was successful in that students enjoyed the interaction together"*. Most electronic students do report that their rapport with their instructor has developed during the course (although this varies among instructors). Instructors report that students are adapting to the medium, too: *"...students are getting used to the idea of sending comments or queries with their messages..."*

jokes: It may be worth noting that the instructors' most common answer to *"What can't you reproduce in electronic tutorials"* is *"the jokes"*. But in the 'successful interaction' groups, there is plenty of humour.

instructor buzz: Instructors get value from face-to-face tutorials, too, which many lose in electronic tuition: a satisfying 'buzz' from the interaction with the students. Some do not view electronic tutorials as enjoyable. Contributing to this perception are a lower rate of interaction and a lack of feedback -- instructors do not get immediate reassurance that the students are understanding them, the interaction is less intense, they cannot count heads, etc.

preparation and quality of teaching: The instructors who participated in the 1996 trial were all experienced, highly-regarded instructors. They already had a repertoire of effective practice in face-to-face tutorials; and they already had material in hand. What success there was is attributable to the excellence of the teaching: the careful preparation, the nature of the setting and structure, the guidance, the quality of interaction, the ability to re-phrase explanations, appropriate milestones, time invested, and so on--including the ability of these instructors to adapt to the new medium. But the failures are *not* attributable to the instructors; in many cases, the same model -- even the same material -- had been a success in another group.

With feedback uncertain, instructors must be prepared to hold a tutorial 'in a vacuum'. Explanations previously offered on-the-fly from notes must be presented in coherent prose, and that prose becomes available for re-reading by the students. More preparation is required, at least initially, than for face-to-face tutorials.

the 'continuous' tutorial: Several instructors proposed (and to an extent implemented) the 'continuous' tutorial, with some problem or question current nearly all the time, but with topics rolling over on a regular basis. Obviously, this requires more instructor time, and it must be monitored and revitalized if it flags.

scope of material: Some instructors claim that they cover *more* material in electronic tutorials, and that they can tackle more realistic problems, in part because the tutorials last longer, and in part because they can be cumulative. However, several instructors have expressed concern that they aren't really able to present alternative forms of information; whatever they do is largely in text, rather than through more direct interaction: *"We can't stand up and wave our hands about."*

group work: Although several of the group work tutorials were considered successful, instructors found it difficult to initiate group working (as evidenced by the few examples), and there is clearly a need for better mechanisms for group working. Two ingredients of the successful groups were 'registration', so that students had to sign up for the tutorial in advance, and role playing.

replayable material: One benefit of electronic tutorials is that most are automatically recorded and can be reviewed 'off-line' either by participants or non-participants. This was an advantage in off-setting some of the problems; for example, difficulties in synchronising a geographically-dispersed tutorial group are balanced by opportunities for automatic recording and replay of interactions. At least one of the instructors who ran IRC tutorials distributed the log files to all students in that tutorial group.

diagnosis: In conventional distance teaching, diagnosis is concentrated in the face-to-face tutorial sessions. In Internet teaching, diagnosis has become decoupled from the tutorial, so that diagnosis is a continuous activity on email. Some instructors introduced regular diagnostic mechanisms, such as a fortnightly query to students on their understanding of some aspect of the course, or just a question about whether they were comfortable with the material. Sometimes asynchronous communication can be disadvantageous when trying to diagnose a particular student problem. Instructors have remarked that students show a reluctance to commit things to the record, and hence they are concerned that problems may remain unexpressed.

demands on students: Instructors wondered about the demands on students: *"I'm worried that we're loading the students too heavily."*-- requiring more time and effort from each student. Asynchronous collaboration with other students involves longer elapsed time, whereas collaboration in a conventional tutorial happens within a fixed couple of hours. And 'passive absorption' is less obviously available: *"You want an element of 'sit back and take this in' and it will help you--I find that hard to put into an electronic tutorial."*

supporting materials: Experience emphasizes the additional need for supporting materials: post-mortems, examples, structured reviews--material that reiterates, re-illustrates, and emphasises the structure of course materials. One instructor instituted the 'tutorial checklist': a list of what the student should understand after the tutorial.

Lessons:

Opinion on electronic tutorials is divided: some groups work, and some do not. On the basis of these trials, we cannot attribute failure to any particular model, nor can we attribute it to any particular instructor. We can, however, list some factors we believe contribute to success, whatever the model.

The key seems to lie in bringing the social interaction alive. Some instructors and students seem to achieve this through asynchronous text, whereas others may need a 'social starter': a face-to-face tutorial, IRC, video -- some way of conveying personalities within the group. Humour matters: most instructors complain that they don't get a chance to joke, but the successful tutorials had plenty of humour in them. Humour is an important enlivener.

Students are surprisingly resilient, especially when the choice is between electronic tutorials and nothing. Students adapt to the technology, the protocols, the limitations, the possibilities.

Structure matters: most of the successful tutorials were presented in stages, with clear tasks and milestones, and a clear review of the material covered. In the first presentation, this entails considerable preparation; but in subsequent presentations, or within a different structure of team teaching, that preparation could 'pay off' in re-use.

At this level of technology, electronic tutorials are no substitute for face-to-face tutorials, although they clearly have value and tremendous potential. And yet the potential must be realized at this sort of level--where technology is inexpensive and available--so that technology makes education accessible rather than exclusive.

The Design of a Cognitive Flexible Hypertext Learning Aid to Teach a Structural Model of Implementation.

Abstract: The design of a Cognitive Flexible Hypertext Learning Aid to teach a structural model of Information Systems Implementation is discussed. Advantages of using a nonlinear medium, such as hypertext, as a learning aid are the freedom to examine information in any order, the possibility to organize any type of information, and, to find things and absorb ideas easier and faster. Constructivism assumes that individuals learn better when they discover things themselves and when they control the pace of learning. The Cognitive Flexibility Theory claims that revisiting the same material, at different times, in rearranged contexts, for different purposes, and from different conceptual perspectives is essential to attain the goals of advanced knowledge acquisition. These concepts were used to design a learning aid to teach the [Lucas et al. 90] structural Information Systems Implementation model.

Hypertext/Hypermedia

Hypertext, Hypermedia, a computerized form of information, is seen as nonlinear prose, interactive print, or dynamic text. It is usually defined as the nonlinear viewing of information. "Nonlinear" means that information can be examined in any order by selecting the topic to see next. It provides a new way of accessing and organizing any type of information. Hypertext can make it easier and faster to find things and absorb ideas.

Researchers and practitioners of hypertext claim that it will revolutionize information systems and cause designers of information to reexamine widely held beliefs and practices relating to publishing, text and screen design, information access and retrieval, user support, and documentation management. Hypertext's cognitive power comes from visually representing the hyper web on the screen to show available links and nodes or updated user paths. Hypertext provides a mental model for representing ideas by transforming the unobservable into objects that can be examined and inspected. Hypertext systems are being used extensively nowadays in many fields, from software engineering to collaborative problem solving applications, as on-line documentation, information retrieval and help systems, as writing aids, and more recently as authoring tools for instruction and learning.

Hypertext, Learning and Education

Historically, instructional usage of computers for training and learning has evolved through different stages: In the 1960s and 1970s, a variety of computer-assisted instructional (CAI) programs were developed. Most of these programs, however, did not meet the expectations that educators had for the new medium. Learning and training via computers were usually based on inflexible presentations of didactic material. Early teaching programs were limited by the hardware then available, and by the only available guide for instructional development: Behavioral Theory.

During the 1980s, Integrated Learning Systems (ILS) were created. ILS are the integration of hardware, software, and curriculum for instruction. These systems are accountability driven, providing continuous performance feedback (i.e., how many questions were answered correctly, how many were wrong, how many were completed). Thus, even though trainees or learners may be working on a variety of topics, skills, or tasks, the system gives the trainer or instructor a very detailed analysis of what work has been done at each station.

Researchers in Artificial Intelligence and Cognitive Science have recently developed additional types of training and educational software: Intelligent Tutoring Systems (ITS) and Cognition Enhancers or Computer-Based Learning Aids (CBLA.) Among the emerging cognition enhancers, we can group those known as *Empowering Environments, Hypermedia*, and *Microworlds* [Brown 85]. The concept underlying a cognition enhancer is that the complementary cognitive strengths of a person and an information technology can be used in partnership [Salomon et al. 91]. Still, the cognitive attributes of human beings give them an advantage over computers in applying peripheral real-world knowledge to ill-structured problems.

Results from preliminary studies have suggested that hypertext-based systems can be usefully applied in training and learning and that it is worthwhile to generate further material for this medium [Locatis et al. 89; Hammond 89; Duffy and Knuth 90; Ess 91; Jones and Spiro 92; Michalak and Coney 93; Madigan et al. 94]. Although all these research studies have proven the usefulness of hypertext technology for training and learning, still no one has demonstrated any appreciable advantage for hypertext. Like many new technologies brought to education, more claims have been made on hypertext's behalf than the experimental evidence has been able to support. Our position here is that hypertext is not the solution for every problem in education, but it is a solution for some problems. The sort of problems that by using hypertext's unique structure either lessen the complexity of the problem and/or ease the learning process. The challenge is twofold: to find those problems, and to implement them successfully in hypertext.

Constructivism

In brief, Constructivism is a theory of knowledge derived from the philosophical proposition that reality is created or constructed by the individual. Constructivism claims that reality is more in the mind of the knower, that the knower *constructs* a reality, or at least interprets it, based on her own perception. While the emphasis in *objectivism* is on the *object* of our knowledge, *constructivism* is concerned with *how* we construct knowledge. Knowledge construction varies with experiences, mental structures, and beliefs that one uses to interpret objects and events.

Radical constructivists believe that there is no real world, no objective reality independent of human mental activity. A less radical approach holds that the mind is instrumental and essential in interpreting events, objects, and perspectives in the real world, and that those interpretations comprise a knowledge base that is personal and individualistic. According to these less radical constructivists, thinking is grounded in perception of physical and social experiences, comprehended only by the mind. What the mind produces are mental models that explain to the knower what he or she has perceived. One important epistemological assumption of these theorists is that meaning varies with how the individual creates meaning from his or her experiences.

The constructivists' views can be summarized as: (1) There is a real world that we experience. (2) Meaning is imposed on the world by us, rather than existing in the world independently of us. (3) Meaning is seen as rooted in, and indexed by, experience [Brown et al. 89]. (4) Constructivists emphasize "situating" cognitive experiences in authentic activities, such as *Cognitive apprenticeship* [Collins et al. 89]. (5) There is no ultimate, shared reality, but rather a reality that is the outcome of constructive processes.

A major assumption is that individuals learn better when they discover things themselves and when they control the pace of learning. The purpose of instruction moves away from knowledge dissemination towards knowledge creation. The process of creation is more important than the knowledge created, since it can be redesigned later, when new connections or structures are developed.

Following the interpretation of [Spiro et al. 88] we see constructivism in learning and education as a new understanding, constructed when various sources of knowledge are put together. With such an interpretation, they developed the Cognitive Flexibility Theory, which adds a new element of constructive processing to those already accepted within Constructivism, an element concerned mainly with the flexible use of preexisting knowledge (i.e., new understandings are constructed by using prior knowledge to go beyond the information given; preexisting knowledge is itself constructed on a case-by-case basis.)

Cognitive Flexibility Theory

Cognitive Flexibility Theory is a conceptual model for instruction based upon cognitive learning theory and attempts to avoid oversimplifying instructions, provides multiple representations of content, emphasizes case-base instruction, focuses on context dependent knowledge, and supports the natural complexity of the content domain to foster the development of advanced knowledge, particularly in ill-structured knowledge domains [Spiro et al. 88.] Cognitive Flexibility Hypertexts are designed to engage learners in more meaningful, transfer-oriented, advanced knowledge acquisition.

The central claim of Cognitive Flexibility Theory is that revisiting the same material, at different times, in rearranged contexts, for different purposes, and from different conceptual perspectives is essential to attain the goals of advanced knowledge acquisition. Content must be covered more than once for full understanding to a point that associations among elements will become apparent. If some of these associations are not grasped on a first exploration, they may be noticed on a second or third attempt.

If we take into account all the previously mentioned factors, it's simple to see that the main metaphor employed in the instructional model derived within Cognitive Flexibility Theory is that of the crisscross landscape [Spiro et al. 88.] This metaphor suggests a nonlinear and multidimensional traversal of complex subject matter, returning to the same place in the conceptual landscape on different occasions, coming from different directions. The instructional model suggests that hypertext, with its nonlinear properties, is a viable technology for building this crisscross landscape.

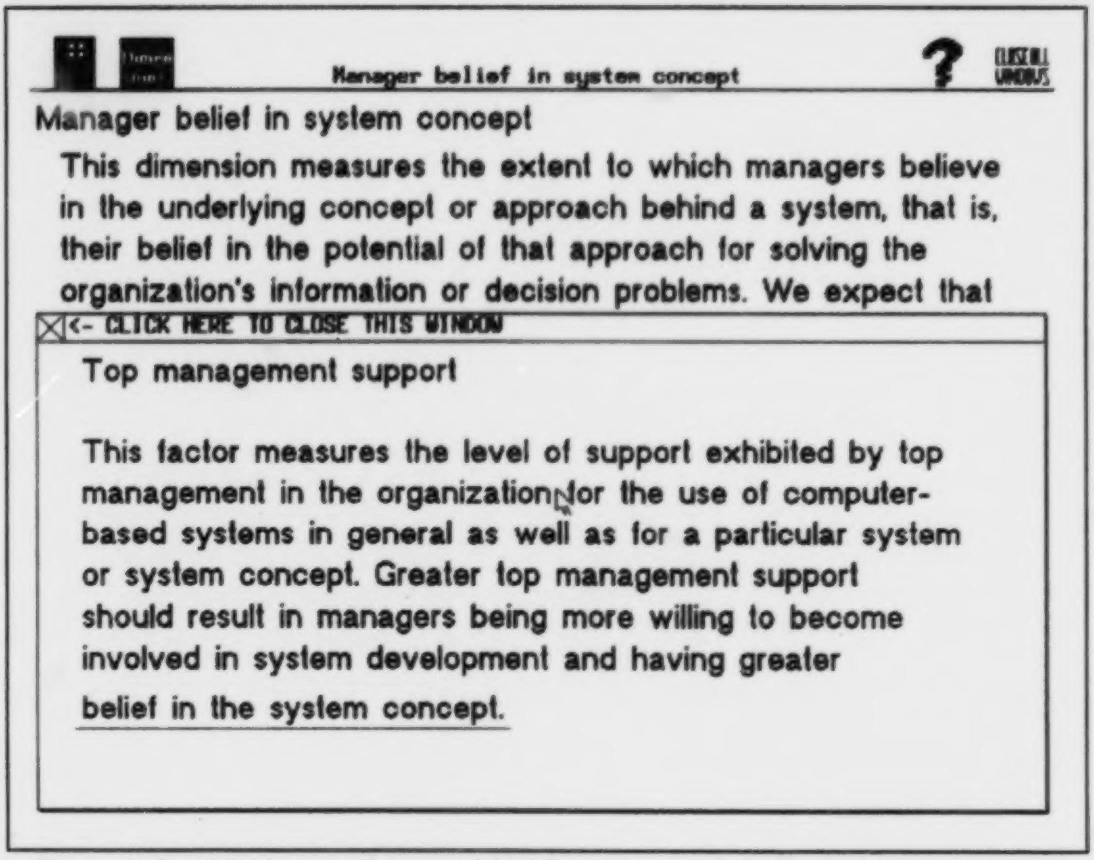
The Design of a Cognitive Flexible Hypertext Learning Aid.

[Lucas et al. 90] developed a structural model of implementation that incorporates many of the results of past implementation research studies. It is based on the research traditions of causal modeling, attitude modeling, and innovation process modeling. They use this approach to explain the phenomena of systems implementation with a conceptual model rich in theoretical implications but complex. Its complexity has been a deterrent to its inclusion in the Information Systems (IS) Curriculum.

The variables included in the model are based on the research findings of previous implementation studies. The model consists of two separable submodels, the *user model* and the *manager model*. The logic of the model is that implementation begins with management initiation and acceptance of a given IS and ends with user satisfaction with the system. Factors leading to manager acceptance are personal (*Manager Decision Style, Manager Demographics*), task related (*Manager Job Characteristics*), and system-specific (*Manager Knowledge of System, Manager Assessment of System and Support*). *Top Management Support* is seen to influence both *Manager's Belief in the Systems Concept* and *Manager's Involvement* with systems development. Beliefs and involvement do not directly lead to *Acceptance*; rather stronger belief leads to more involvement. Also, both stronger belief and more involvement lead to more knowledge of the system. All this to say, that some factors depend on other factors which increases the complexity of the model.

The *manager model* was implemented in Hypertext by the author under the light of Cognitive Flexibility Theory. The Hypertext module consists of nine screens and ten windows. Each dimension (Manager Belief in System Concept, Manager Knowledge of the System, Manager Assessment of System and Support, Manager Involvement, and Manager Acceptance) is presented on a screen. These screens contain their definition and links to the factors or dimensions that have a direct influence on them. Through the links, the windows containing the information of the factors and influencing dimensions are presented when a link is selected. Links are filtered through programs that highlight the relevant information concerning the selected factor or influencing dimension; this is one of the powerful characteristics of hypertext that provides reinforcement in the learning process [Fig. 1 and 2]. The screens also contain linear links through labelled arrows that allow the user to traverse the information sequentially.

This design besides providing reinforcement in the learning process, directly uses hypertext's cognitive power. As mentioned previously, by showing available links and nodes on each screen, learners visually construct the hyper web which is a representation of the expert's mental model. Also, by revisiting a given factor or dimension, at different times, from different variables with different highlighted information, associations will become apparent.



Dimen sions
Manager belief in system concept
?
CLOSE ALL WINDOWS
<- CLICK HERE TO CLOSE THIS WINDOW

Manager belief in system concept

This dimension measures the extent to which managers believe in the underlying concept or approach behind a system, that is, their belief in the potential of that approach for solving the organization's information or decision problems. We expect that

Top management support

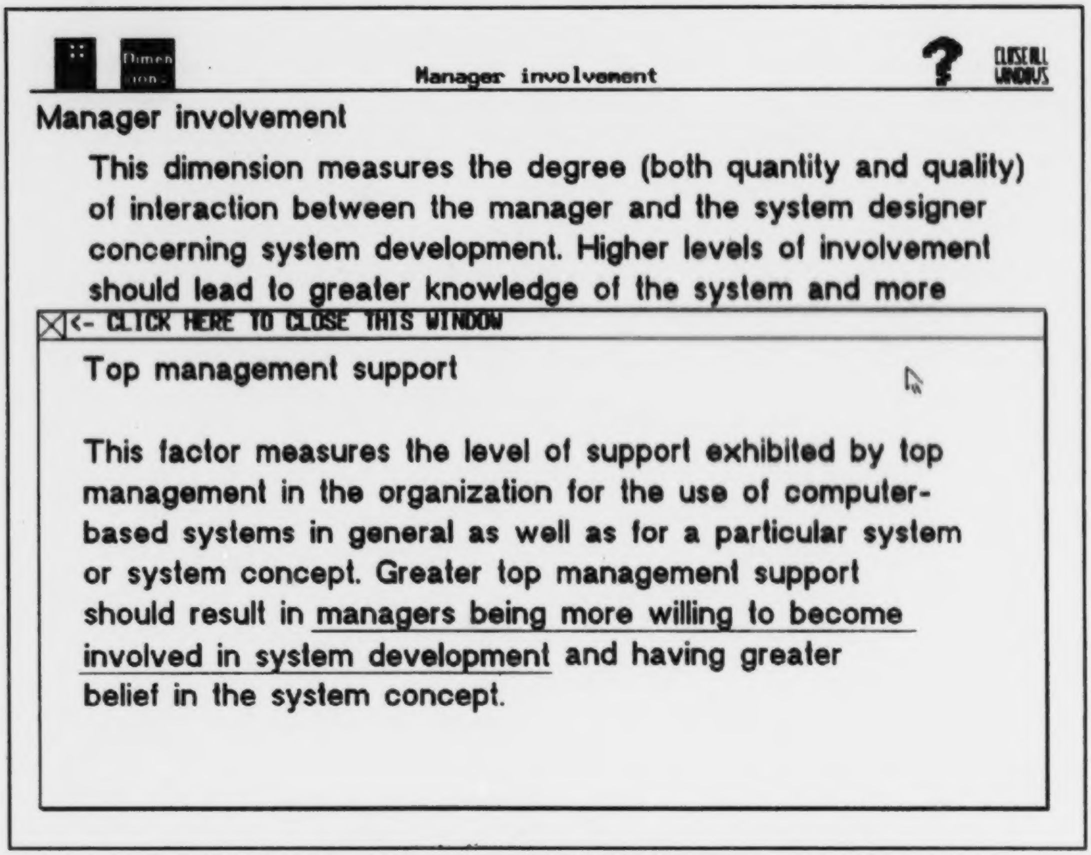
This factor measures the level of support exhibited by top management in the organization for the use of computer-based systems in general as well as for a particular system or system concept. Greater top management support should result in managers being more willing to become involved in system development and having greater belief in the system concept.

Figure 1: Top Management Support visited from Manager Belief in the Systems Concept.

This is some kind of a cognitive "click" which allows learners to "know" that they have learned something new.

The module also includes five linked icons: *Dimensions, Close All Windows, Help, Notes* and *Exit Door*. With the *Dimensions* icon, users can revisit the dimensions' screen containing a brief explanation of the model and links to each dimension. The *Close All Windows* icon allows users to close all open windows and keep on working in the active screen. *Help* opens a window containing a list of the possible actions to take given a particular situation. The *Notes* icon opens an online file where users can type some notes. Once the online file is open, a sixth icon is presented: the *Printer* icon allows users to print the contents of the online file, if there is a printer available. Students may quit the application using the *Exit Door* icon.

All these elements are put together to allow learners to experience the model actively instead of passively. Learners can move back and forth within the model to "discover" the relations between dimensions and factors. These relations also help the understanding of the dimensions and factors themselves.



Manager involvement

This dimension measures the degree (both quantity and quality) of interaction between the manager and the system designer concerning system development. Higher levels of involvement should lead to greater knowledge of the system and more

Top management support

This factor measures the level of support exhibited by top management in the organization for the use of computer-based systems in general as well as for a particular system or system concept. Greater top management support should result in managers being more willing to become involved in system development and having greater belief in the system concept.

Figure 2: Top Management Support visited from Manager Involvement.

Strengths and Limitations

The model was designed within the philosophy of constructivism. One of the assumptions that work well in this model is that meaning varies with how the individual creates meaning from his or her experiences. Unless learners choose to traverse the information sequentially, no two learners will have the same experience. Each of them will create her or his own construction of the same implementation model. That does not mean one will be right and the others wrong; the model is the same, just the understanding of it will be different.

An important feature of the learning module is that it allows learners to selectively visit each dimension and the factors/dimensions that have a direct/indirect influence on them. This option provides a way to show the pattern of association (by means of the highlighted information) which reveals the conceptual information of the model. Then, by exploring, in a constructivist manner, students are actually learning.

One important limitation is the fact that complex models are difficult to implement. The amount of information necessary to show differences that exist mainly in perception can escalate rapidly. Sometimes it may be unfeasible to attempt it; in others may be irrelevant. One of the most important learning experiences, derived from this design, is the acknowledgement that finding a workable balance between feasibility and relevancy is the main goal when designing instructional material for hypertext.

The main limitation of using hypertext in learning has been determined to be disorientation (*lost in hyperspace*.)

To prevent this problem, the module contains the *Dimensions* icon, which takes students to the first screen of the module. Therefore, every time a student needs to revisit the list of dimensions, wants to visit a specific screen, or does not know what to do, by clicking on the *Dimensions* icon, he/she will be able to get back to a "safe" location. The title of each screen refers to the dimension under discussion. The *Help* icon provides information on the options available any time it is requested. With all these aids, disorientation is unlikely.

Implications for Future Research

Hypertext is not the solution for every problem in learning. There are many aspects of learning where hypertext does not have a meaningful contribution. What is needed then, are some criteria to determine which aspects of the learning process are better served with hypertext. Those areas where information is not linear, or where by imposing linearity the information is not oversimplified, are excellent choices.

The new hypertext learning aids should foster learning by discovery in a constructivist way, bring some kind of structure to ill-structured material, and allow material to be revisited at different times, in different contexts. If the amount of information is overwhelming, it should be broken into modules and meaningful links should allow the traversal of each of them from different parts of the system. If necessary, the system should provide "guided tours" to the information. One aspect to investigate on these guided tours, is whether they promote motivation to learn.

The next step in our research will be to test the benefits of learning using the hypertext module. Currently we are conducting a pilot study to validate the module. Later we will conduct a controlled experiment to measure differences in performance in a problem-solving situation, if any. We expect to find evidence to support the claim that performance will increase proportionally to the complexity of the problems to be solved by those subjects using the hypertext learning aid.

CourseWeaver
A Tool for Building Course-Based Webs

Samuel A. Rebelsky
Dartmouth College
Hanover, NH USA
samr@cs.dartmouth.edu

Abstract: Many instructors find the development of course webs difficult because few web development tools provide the many facilities that course webs often require. One such requirement is that for multiple "views" of the same collection of information: one designed to be navigated online, one to be printed and distributed. Another is an appropriate way to ensure that pages are formatted in the same way and to propagate design changes. CourseWeaver is a freely distributed tool for building course webs, whose development is based on experience constructing and evaluating student use of course webs [Rebelsky 1994, 1996]. CourseWeaver is designed to meet the needs of the typical course web designer, particularly one with little experience. As such, CourseWeaver prompts for appropriate components, automates much of the construction of course webs, permits easy reorganization and multiple views of course webs, and accommodates significant customization. This paper reports on the motivation, design, and applications of CourseWeaver.

1. Introduction

The enormous growth of the World-Wide Web (WWW) [Berners-Lee et al. 1994] has led a number of instructors to begin to build webs of resources for their courses. Yet the design of a useful course web is still a complex process, involving many steps that can be partially or fully automated. These steps include,

- HTML markup, which many prefer to do using fully or partially WYSIWYG ("what you see is what you get") tools.
- Appropriate reuse of previously developed materials, particularly materials developed for a prior session of the course.
- Uniform formatting (and reformatting) across web pages, not only to give the site a uniform "feel", but also so that students can develop strategies for reading pages.
- Overall web organization, which will be similar for many courses.
- Presentation of course materials in multiple forms — not only (1) online webs with small pages, but also (2) printed pages that collect together smaller pages, and (3) stand-alone applications.
- Version control, so that prior versions of the web may be made available, and so that it is clear what changes have been made.
- Construction of outline-like components, such as the course syllabus or tables of contents at the beginning of printed pages.
- Extendibility, so that new kinds of components can be easily added.

CourseWeaver is a free application designed to meet the needs of the course designer. It guides the web designer through many of the steps in course web design, automatically generates multiple versions of the course web and of navigational structures and allows more advanced web designers to add new templates and change the design of web pages. The following sections further explore the design, use, and benefits of CourseWeaver.

CourseWeaver's Model of Course Webs

A CourseWeaver web consists of an extended collection of basic information elements (hypertext nodes) arranged within the traditional course handout structure (e.g., assignments, class outlines, informational guides). It differs from the traditional handout structure in that components can be freely reused and refer to other components. To facilitate design, organization, reuse and configuration of course webs, CourseWeaver employs three general structural classes in describing webs: nodes, documents, and sites. Both nodes and documents may appear in a variety of specialized versions (e.g., each type of handout is a specialized version of the document class). Each component of CourseWeaver web is an instance of one of these generic or specialized structural classes. For example, a particular assignment is an instance of the assignment class, which is itself a specialized version of the document class.

CourseWeaver *nodes* are small pieces of information (at most a few paragraphs) which provide the primary data that the site presents. In addition to generic nodes, CourseWeaver also provides problem nodes (nodes which are extended to include complexity levels, point values, and other pertinent information) and example nodes (which are extended to include links to corresponding problems and ideas). Although CourseWeaver does not enforce a particular node size, good hypertext design suggests that nodes be kept small (e.g., [Berners-Lee 1994] [Nielsen 1996]).

CourseWeaver *documents* are hierarchical collections of nodes (or, more accurately, references to nodes). Documents resemble the high-level outlines instructors often use when writing handouts -- they describe organization, but not detailed information. Documents provide the low-level structure for the web, as they describe the relationship of different nodes according to a particular use of those nodes. Each document effectively presents a trail [Bush 1945] through a subset of the nodes — an organized sequence that provides one way to traverse the web. Because these trails may be written as hierarchies, they can also provide high-level overviews of how to traverse documents (e.g., one can only look at the top level nodes, without descending into further details.) Documents also provide context for individual nodes, so that a student navigating a CourseWeaver site can determine how the current node is used and what materials are pertinent to that node in various trails through the web.

CourseWeaver *sites* provide the high-level structure of course webs. Each site lists (1) the classes of components used in the web; (2) the names used to describe each class; and (3) the components within each class. The class/name pairs provide a simple context for each document and allows designers to use the same class in multiple ways. For example, one might use the assignment class for laboratory assignments, homework assignments, and perhaps even quizzes and exams. Components within each class are listed so that they may be numbered (providing some context).

Every components of a CourseWeaver structure contains a number of elements that may be filled in by hand or automatically by CourseWeaver. All components contain

- one or more *labels*, which are used for hypertext links and references;
- a *title*, which is used in generating pages, and in building the default text for links;
- a *version number*, which permits both updates and historical views;
- a *creation date*, which is primarily used for information purposes;

- a *modification date*, which is used to inform students of updates and to permit "snapshots" to be taken of a structure (e.g., an instructor can automatically extract the version of a web for a particular date); and
- a *release date*, which aids in building syllabi and ordering components.

An author need fill in only title, as CourseWeaver can automatically generate the remaining fields. However, authors are allowed to fill in the remaining fields.

Three dates are used because each plays a separate role or roles. The creation date is used primarily for historical overviews, but can also be used for notification purposes. Since many instructors create materials long before they use them, the release date provides a within-course context for each component (so that a student knows when a piece of information becomes "valid" for the course or so that CourseWeaver can only incorporate released materials). The modification date helps students (and instructors) keep track of changes and allows CourseWeaver to manage a history for the structure.

Other components may include additional elements. In particular, nodes also contain data fields, documents contain node hierarchies, and sites contain document hierarchies. Similarly, specialized classes include still more information. For example, assignments may also include a due date, an expected length, and a set of readings. CourseWeaver employs this "fill-in" based authoring for a number of reasons, particularly to ensure uniformity among pages and to help ensure that novice course web designers remember to include pertinent information.

Other than this three-level segmentation, CourseWeaver does not significantly restrict the ways in which each class can be used. There is no restriction against reuse; or example, the same node can be referred to by multiple documents and the same document can be used not only by multiple sites, but also in multiple positions within the same site. There is also no enforcement of use; for example, one can build a site that only uses some of the documents in the CourseWeaver collection. However, unused portions will not be available when CourseWeaver builds a web from the components.

Weaving CourseWeaver Webs

After writing the components, the instructor can ask CourseWeaver to build an appropriate set of HTML pages for online and printed versions of the site. Each component is translated to conformant HTML in a slightly different manner.

The site overview is generally presented as a table of contents with links to the page for each document. The site is also broken down into smaller tables of contents for each named document class. In a typical class, there would be separate tables of contents for guides (tutorial documents), notes, homework assignments, exams, and quizzes. If the web designer chooses, the site can also be presented in syllabus form, using the release date to determine where in a syllabus each component belongs (and prompting the designer whether or not each component type is include).

Each document is presented in two ways. For online use, each document is presented as a simple table of contents with links to the translated nodes. If the web designer so chooses, the table of contents can be in a dynamically expandable form (as in Macintosh System 7's view by name) using automatically inserted JavaScript or VBScript commands. In addition, each document is also presented in a compound form, with each component node on the same page (and their titles at the appropriate heading level). The compound form is primarily designed for printing, although some readers prefer the longer online compound forms, which require less jumping between pages. This compound form also includes a table of contents, which many readers find significantly helpful when navigating the printed version [Krug et al. 1989]. Finally, each document page contains links to the next and previous documents in the site sequence and to their position in the course syllabus.

Central to each node are the title and body (information) of the node, but CourseWeaver supplements these with additional contextual and navigational components. In particular, each node begins with a series of *contexts*—for each document that contains the node, the document name and ancestors of that node within the document are given. In addition, each node also includes a *previous* and *next* links, with one set of links per context. Finally, each node is annotated with *dates* and *version* number (and, if the web designer chooses, links to earlier and later versions).

The initial and terminal contexts added by CourseWeaver help prevent readers from getting "lost in hyperspace" [Nielsen 1995]. In addition, if the web designer chooses, CourseWeaver can add JavaScript code to highlight the current context used, which is determined by the way the document was entered, and is shown by presenting the current context in an alternate typeface.

As an alternate to these many contexts and links, a web designer may choose to have CourseWeaver generate multiple copies of each node, one for each context. There are distinct benefits to this choice. For some readers, the proliferation of contexts may be detrimental rather than helpful. For such readers, a linear structure is preferable to a complex hypertext [Lanza and Roselli 1991]. By making separate copies, the reader only has one path to follow at a time, and it's easy to return to that path if one strays from it. However, multiple contexts may be appropriate for more experienced users, as they not only orient readers, but suggest new paths of exploration.

While CourseWeaver is primarily intended to generate these HTML-based web, CourseWeaver can also build a stand-alone version of a site. This step preserves the overall form of the CourseWeaver structure, but also (1) locks all components (so that students cannot modify them); (2) adds a area for students to take notes on each node; (3) removes some components (all but the selected site, any documents and nodes that are not referenced); and (4) adds context and links (similar to those generated for the HTML version).

Obviously, each web designer will approach web construction in different ways. Some may choose to include different types of documents or nodes, others may wish to use more sophisticated formatting or incorporate Java applets in some pages. CourseWeaver provides four basic mechanisms for generating custom sites:

- prompts for basic decisions (e.g., how to present contexts or how different elements are represented textually);
- a class generation facility, so that site authors may design, use, and share their own classes;
- customizable HTML translation, so that different designers may present elements of nodes in different ways; and
- access to the underlying implementation, so that more sophisticated users can modify CourseWeaver itself.

Comparison to Other Web-Construction Strategies

There are a number of tools that help with some aspects of the construction of course webs, including text editors, page-level authoring tools, translators, site-level authoring tools, and Perl scripts. CourseWeaver's emphasis on logical design and uniform presentation, reliance on a three-level structure for creating webs, and use of a "fill-in" strategy for authoring provides some advantages and disadvantages when compared to these other systems.

Text editors, such as BBEdit [Bare Bones 1996] with accompanying HTML tools [Davies 1996], allow web designers to build templates for their course materials, permitting uniform formatting across web pages. Text editors may also provide tools to automate the insertion of HTML tags, so that web designer need know only minimal HTML in order to create pages and still have great control over their pages. However, many users find it difficult to reformat a large number of pages using text editors, and few text editors provide appropriate mechanisms for version control, automatic outlining, and presenting of information in multiple formats.

WYSIWYG page-level authoring tools, like Navigator Gold [Netscape 1996] and Pagemill [Adobe 1995], allow web designers to construct HTML pages without having to know or understand HTML. . Since CourseWeaver's primary emphasis is on hyper*text* and node-based information systems, it provides only minimal facilities for handling In more complex pages where images or layout are particularly important, the WYSIWYG tools are preferable. However, such tools often provide little help for site-level authoring, for reformatting a large number of pages, or for presenting the same information in multiple formats.

Translators, such as LaTeX2html [Drakos 1995 permit web designers to convert materials generated in other pages to HTML, again, without having to know or understand HTML. Some translators make also it possible to present the same information in different size chunks. However, users often have little control over the translation (which may be based more on the physical layout of a page, rather than the logical layout) and the sites created by automatic translators may be difficult to update or extend. It is also important to note that CourseWeaver does present some translator-like facilities. In particular, each node is automatically translated from text to HTML, with appropriate insertion of paragraph, list, emphasis, and related tags. One CourseWeaver user has found this translation particularly appropriate for translating rough class notes to HTML.

Site-level authoring tools, such as ASML, the Automated Site Markup Language [Frank et al. 1996], facilitate uniform formatting and reformatting for web pages and may also provide additional translation tools and support capabilities (e.g., ASML allows site designers to automatically build multiple search tables containing only part of the site). Many also require authors to learn a new language, which may be difficult for some. For the advanced user, ASML and similar authoring languages have many advantages, as they provide much more control over the structure of the site.

Scripts written in languages like Perl can provide additional facilities, such as automatic construction of outlines. However, they require advanced knowledge to use and reconfigure both the generated HTML and the facilities they provide. CourseWeaver is perhaps weakest on this programmability front, but tries to alleviate some of these limitations by providing access to the underlying implementation.

Finally, full-scale hypermedia authoring systems, such as HyperWave [Maurer 1996] provide extensive authoring, re-authoring, and presentation capabilities. HyperWave, in particular, provides many of the key features of CourseWeaver, including automatic contexts and overviews, some fill-in type authoring, and a class hierarchy. CourseWeaver's primary advantages when compared to a system like HyperWave are its smaller size, its inclusion of predefined templates for educators, and its ability to generate pages whose names have some meaning.

Summary

Instructors creating webs of information for their courses benefit from utilities that automate or simplify aspects of the creation. While there are a number of tools to help authors, each of these tools solves only a few of the problems in creating a course web. While it is possible to use an ad-hoc combination of tools to meet more problems, CourseWeaver provides a single application that is focused on the specific needs of course webs. CourseWeaver not only guides instructors through the creation of webs, but also presents ideas (such as multiple views of the same web for online, off-line, and printed use) that many instructors might not employ without automation.

Abstract: This paper presents the result of an experiment designed to evaluate the impact of hypermedia software in learning The experiment was carried on with students aged 10 to 11, from three different schools. The experimental design contemplated four groups in each school, 9 students per group, totaling 27 students from each school, and exposing them to courseware about the biology of the human body, either in a full multimedia modality; a linear electronic book format or a printed booklet with the same information. An additional control group received no experimental treatments, but was exposed to the same content materials, through regular classes. The results of the experiment showed that all students increased their retention of information exposed to during training, but the group that was trained through hypermedia software obtained significantly higher scores in metacognitive capabilities such as semantic relatedness and knowledge structuring through a concept mapping task

1. Introduction

The idea that organizing software using a hypermedia based structure can have an impact on student's learning performance is not new. In fact, many authors have suggested that this way of organizing and presenting information enables students to develop search strategies and thereby exercise "higher" metacognitive skills (Engelbart, 1963), enhances the acquisition of conceptual structures (Spoehr, 1994) and allows for self-instruction in a self-paced exploration, according to the users' own interests.

However, there is still a lack of evidence about its real effectiveness and about the areas of its potential impact (Jacobson, 1994). Some authors have addressed problems related to hypermedia such as cognitive disorientation, cognitive overload (in combination with multimedia), inconsistency of links and lack of meaningful links (McKendree, Reader & Hammon, 1995).

In this scenario of pros and cons of hypermedia, the question addressed here is if hypermedia has an impact in the areas of content retention, cognitive association and conceptual mapping. In this sense, we restrict the question of impact to this three specific areas of potential impact.

2. Subjects and Procedure

The main purpose of this study was to investigate whether hypermedia support effective learning. Operationally, the authors explored the effectiveness of a software using a hypermedia based structure, on student's ability to retain a given information, to understand its more complex levels of interrelatedness, and to represent the knowledge structure resulting from its accretion to the students' prior knowledge framework.

These questions were addressed by randomly assigning 5th grade students (ages ten to eleven) from each of three different schools, into each one of four groups of 27 students. All students were exposed to courseware about the biology of the human body, either in a full multimedia modality (Group 1); a linear, electronic book format (Group 2); or a printed booklet with the same information (Group 3). There was an additional, control condition (Group 4), which received no experimental treatments, but was exposed to the same content materials, through regular classes (as did all other students participating in the study).

The participating schools were approached because they had just received a computer lab and the students were naive regarding the use of computers and multimedia educational software. All three schools had more than one class at the fifth grade level; however, a single class per school was chosen to participate in the study, based exclusively on the biology teacher's willingness to collaborate with the study. Once the availability of a given class was determined, up to nine students per school were randomly assigned to each group.

The teacher's collaboration was required in terms of (i) accepting to cover this particular subject area of the curriculum, contemporary to the exposure of the groups in the study, to the different treatment and control conditions; (ii) assigning the students weekly research homeworks based on the material covered in class, thus providing realistic motivational conditions for students participating in all groups; and (iii) relinquishing the control of the class once a week so that the investigator's research assistants could ran the successive 12 weekly sessions that took to complete the study. Because of obvious logistic and procedural reasons, all experimental conditions were ran in parallel, in every school, for all students taking part in a given group.

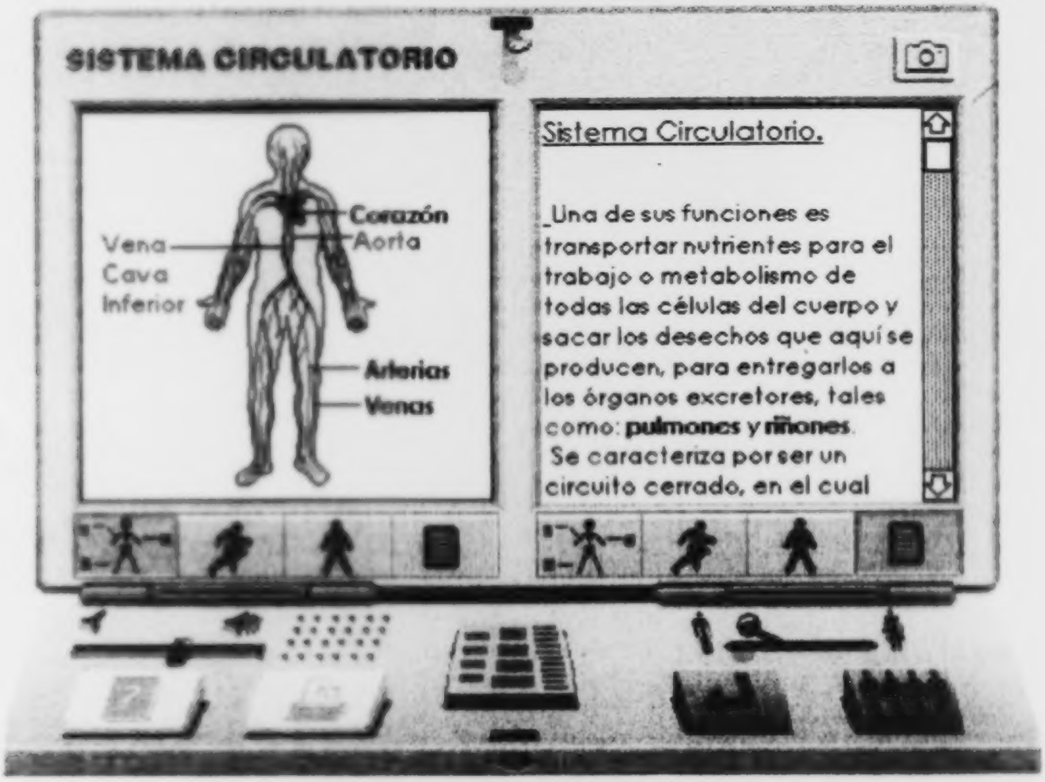
Parallel to this, an agreement had been obtained with the technology coordinator in each of the schools, so that six of the computers in the lab could be used once a week, during the biology class, to work with groups 1 and 2. For this purpose the multimedia version of the software "Centro de Anatomía" (software implemented by the authors) was installed in 3 computers and a version containing a linear sequence of electronic pages of the same content, was installed in the other three computers. Group 3 used a printed version of the latter. Students in the three treatment groups were required to work in groups of three, either in front of a computer, or with the booklet, depending on prior group assignation.

3. Material and Instruments

The software used in the experiment was an adapted version of the software "Centro de Anatomía", which contains text, illustrations and animation about four systems of the human body (digestive, respiratory, circulatory and urinary). The information for each system includes a global description, its principal subsystems and all the major organ of the system. The interface of the hypertext version of the software (Group 1) is shown in Figure 1.

Text and figures contain hyper links to textual and/or graphic information on related organs. The links were implemented following functional (the organ plays a role in the system) or structural (it is a component of the system) relations amongst systems and/or organs.

The linear version of the software (Group 2) had the same user interface, but the links were functionally and graphically disabled (i.e., plain text instead of bold). The paper version (Group 3) was a printout of the text and figures used in the linear version of the software, organized in chapters related to each system.



SISTEMA CIRCULATORIO

Sistema Circulatorio.

_Una de sus funciones es transportar nutrientes para el trabajo o metabolismo de todas las células del cuerpo y sacar los desechos que aquí se producen, para entregarlos a los órganos excretores, tales como: **pulmones** y **riñones**.
Se caracteriza por ser un circuito cerrado, en el cual

Fig. 1: Content Interface of the software used. Main screen of the circulatory system

The Body Knowledge Questionnaire (BKQ), consisted of a set of 40 assertions about parts or functions of the human body, which required a "true" or "false" answer. The test items were built from the same content material included in the software and used during the training sessions. The students' answers to the pre- and post-training applications of the questionnaire were scored using a right or wrong key , previously elaborated by three expert judges.

The Associative Distance Test (ADT), consisted of a set of open questions of the form "Which is the similarity between x and y ?", where x and y were organs or body parts of the same or different systems, which had a relatively closer or more distant structural and/or functional resemblance. The students were expected to respond by specifying those aspects, or dimensions by which, in their understanding, the two elements in the question were related. The assumption behind this questionnaire was that the more distant the elements a student was able to establish a valid associative link with, the greater the metacognitive ability and the amplitude and meaningfulness of the child's representation of the concepts involved. It was further assumed that such sort of abilities would be enhanced in children who had been exposed to hypermedia learning conditions, and therefore, it was predicted that students in Group 1 would obtain a significantly higher score in this test than would students in any of the other three groups. This test was applied once, at the end of the experiment in order to compare post-training performance amongst the groups.

Students' statements in response to the questions in the ADT test were classified according to three different levels of "distance" or abstraction: (a) Concrete responses alluding structural-descriptive features (i.e., "they are circular", "both are microscopic", etc.); which

BEST COPY AVAILABLE

were assigned one point. (b) Responses alluding contextual or situational descriptive features (i.e., "...they belong to the same system"; or "...they circulate in the bloodstream"); these responses received two points; and (c) Responses which made correct reference to functional or behavioural similitude across systems, received three points. The highest score empirically reached by one student in the study was 33 points.

A third instrument, designed to assess the richness and meaningfulness of achieved learning through the structure of resulting knowledge, was a Concept Mapping Task (CMT). Conceptual mapping is a technique devised by (Novak & Gowin 1988) in order to facilitate meaningful learning. The same technique, only this time coupled with a scoring system, was used to assess the amount of learning achieved by students in all groups in the study.

Once the treatment phase of the study was completed, all students received three additional sessions to learn how to build conceptual maps, totally unrelated to the subject area of the experimental training. Immediately after this training, students were given a set of 22 labels of concepts related to the digestive system and asked to build concept maps that would depict the structural (spatial distribution) and functional links amongst these concepts. In the CMT, just as had been the case for the ADT, students in each group were asked to work in the same clusters of three children, they had formed during the training sessions. Afterwards, each map was analyzed and scored according to a revised version of the procedures reported by Novak & Gowin (1988). More specifically, the procedure to score the maps was based on the quality of the relations student's were able to build. Hierarchical relations were scored with five points, crossed connections with 10 points and examples with only one point.

4. Results

Concept Retention. Following the application of all measures, data from each test were tabulated and analyzed. The data obtained with de BKQ the the result using t of student test for related data (the same group scored twice), it was found that in all groups there was an increment of retained concepts. As shown in Table 1, Group 3 (paper booklet) presented the higher increment, followed by Group 1 (hypermedia) and the lowest increment was by Group 4 (control). From these results it can be inferred that concept retention will increase significantly, regardless of the treatment modality used to facilitate learning. However, if the percent of increment between pre and post test is calculated, then a notable difference will become apparent.

Group	t	alpha	%increase
1	11,45	.00000	22,88
2	8,50	.00000	18,93
3	19.47	.00000	20,92
4	17,18	.00000	7,66

Tab.1: Student's t test results for pre and post training score comparisons

In spite that all groups showed significant gains in overall retention scores, we observed important group differences in the magnitude of increment of post-treatment scores. In order analyze this issue further, a Pearson correlation was ran between each subject's pre-training score and the percentage of score increment at the second measurement, following training. These data are shown in Figure 2. As it can be seen he resulting correlation coefficients were negative for all groups, meaning that those students who entered the training with lesser knowledge, gained the most. Interestingly enough, Groups 1 and 2, who used computers and multimedia showed this inverse relationship between prior knowledge and training related gain, at a highly significant level (r=-656, p <.01; and r=-678, p<.01, for Groups 1 and 2, respectively).

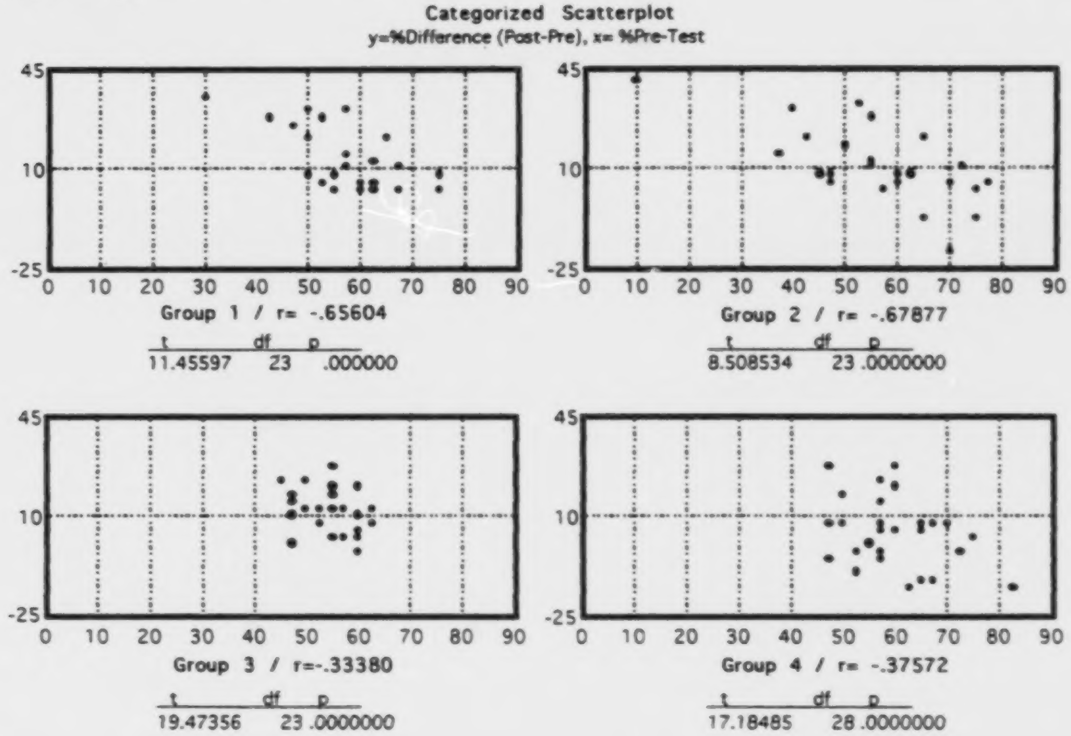


Fig. 2 Scatter plots and correlation between pretest scores and percentage of increment calculated in post-treatment retention scores

Associative Distance Test. The data obtained by the students in all four groups with the ADT test were analyzed by using a one-way Analysis of Variance. The result showed statistically significant differences among the groups [F(3,94)])02.31, p=.04. Specific *a posteriori* contrasts showed that this result was accounted for by the differences between groups 1 and 3 and groups 1 and 4. With this result, we can say that the hypermedia treatment condition, allowed for grater and more meaningful interrelationships of learned information than did the text-based treatment condition, or the habitual classroom activities. However, no significant differences were found between group 1 and group 2, as well as between group 2 and groups 3 and 4.

Concept Mapping Task. The data obtained by the four groups of students in the CMT were also analyzed by performing a one-way ANOVA, which in turn, also showed overall group statistically significant differences [F(3,8)]=12.75, p=.001. Specific *a posterior* contrasts between pairs of means, using Schaffe's LSD test, indicated that group 1 performance was significantly better than that of groups three and four. Again, no significant differences were found between the performances of groups 1 and 2, or that between groups 2 and 3 and groups 2 and 4.

6. Discussion

Preliminary analysis of the results indicate that no significant differences may be found among the groups on the retention of concepts related to body parts and functions. However, the analysis of the percent of gain relative to the level of knowledge the students had on the subject, prior to training, showed that hypermedia software seems to constitute a more powerful facilitator of learning than regular reading or class attendance procedures. On the other hand, it could be said that there seems to be a certain level of knowledge required in order for students to be able to profit by their exposure hypermedia software; and if this level is not present in the user, (s)he will not be able to profit by using the software. This latter notion needs to be tested under lower floor and higher ceiling conditions than the ones used in the present study

On the associative distance test students in group 1 were able to make a significantly greater number of correct far-stretched associations between subtly related pairs of concepts, as compared with students in group 3 and the regular, control group. Interestingly, there were no significant differences between the two software groups (groups 1 and 2). However, the fact that group 2 did not differ significantly from groups 3 and 4, seems to suggest that linearly organized sequences of multimedia based information is not as powerful to promote deep conceptual understanding and awareness of inter relatedness of the learned materials, as does a hypermedia based software.

From a methodological perspective, the question of construct validity (Yin, 1994) is relevant, given the instruments used, were specifically designed for this experiment. This issue is part of an ongoing research, who's aim is to define operational measures for both concepts: associative distance and knowledge and structure. For the time being, and while the instruments results obtained provide a way of comparing the performance between the different groups only.

Related to internal validity (i.e. establishing a casual relationship, whereby certain conditions are shown to lead to other conditions, as distinguished from spurious relationships, (Cone, 1994)) problems like history, maturation and statistical regression are avoided because of the time scale of the experiment (12 weeks only), and problems of testing (effect of the pre-test) were not observed in concept retention. Instrumentation could be an interesting problem, so far the instruments and score methods were invented, but because of the design, this is rather an external validity problem. Problems of selection and experimental mortality were avoided selecting multiple schools and randomly assigning students to each group.

External validity is the most relevant question in this experiment. For example, the difference in content retention between the experimental groups and the control group can be explained by the Hawthorne effect (Cohen, 1994), that is, by the special condition of the experimental groups. Also the results of the other tests must be validated before generalizing. Finding the answers to these issues constitute part of the aims for the continuing research efforts of the authors..

One attempt to prevent this methodological problems, was an attempt to triangulate these data a different set of data captured in each experiment session. Specifically, on every session a log file was automatically produced which indicates the browsing sequence of group one (similar to Misanchuk & Schwier, 1992). This information is still to be analyzed and confronted with the results obtained by each group in the ADT and CMT. In a replica of this study, we hope to find some correlation between the browsing patterns and the associations and the concept maps produced by each student. Since browsing patterns are from each individual and concept maps were built in groups, such correlation was not possible for the present study.

Institute of Distance Education
Korea National Open University, Korea
E-mail: isjung@av9500.knou.ac.kr

Abstract: In the fall of 1995, the Korea National Open University launched a project to research use of the information super-highway with funds from the Ministry of Information and Communication. As a result, an interactive videoconference network was introduced for educational programs in the geographically scattered regional and local study centers. Using this network, the project connected 14 centers, introduced interactive tutorial sessions, held various meetings among university members in different places, encouraged open discussions among students, faculty members, and general citizens, and created non-degree programs using the system. Detailed evaluation has revealed that the majority of the instructors and participants have had a favorable impression of this system. Despite its shortcomings, the investigators have found that VCS is here to stay.

1. Introduction

Most distance learning programs have been delivered in a one-way communication format. Printed materials, audio, video, radio, and TV have been heavily used for delivering the programs. In addition to these media, distance teaching institutes have offered face-to-face tutoring or counselling, e-mail and fax communication services. In recent years, new information technologies(NIT) have exploded and many distance educational institutes have been seeking various ways of incorporating these advanced technologies into their system to improve two-way interactivity and thus to ensure the quality of distance education. This report is based on an evaluation study funded by the Korean Government.

In the fall of 1995, the Korea National Open University (KNOU) launched a project to research use of the information super-highway with funds from the Ministry of Information and Communication. As a result, an interactive videoconference network was introduced for educational programs in the geographically scattered regional and local study centers. Using this network, the project connected 14 centers, introduced interactive tutorial sessions, held various meetings among university members in different places, encouraged open discussions among students, faculty members, and general citizens, and created non-degree programs using the system. Since KNOU serves above 300,000 students and it has 640 faculty members and administrative staff all over the nation, meetings and training sessions among its members were frequently held.

The Korea National Open University(KNOU), one of the world's largest distance learning institutes, was founded in 1972. As the only distance teaching university in Korea, KNOU has continued to serve the advanced educational needs of adults as well as awarding degrees at the bachelor's level to qualified people. As any other distance education institutes, KNOU has adopted printed materials as its main instructional delivery medium and broadcast lectures through TV and Radio as its supportive teaching method. However, most courses require students to attend a one-week schooling session held at the 12 regional centers all over the nation. The purpose of these schooling sessions is to deliver concentrated lectures.

As for the schooling sessions, each regional study center organized the schooling sessions independently from the other centers and thereby provided different contents under the same course titles. Actually individual learning centers hired part-time instructors locally. Most of the time the students in the Seoul area in which the headquarters of KNOU is located received the lectures from the KNOU professors who had themselves developed the textbook materials and examination goals for the achievement tests.

In addition to the 12 regional study centers located in the provinces, 29 local study centers have been established for the students who live in more remote areas. However, to receive schooling sessions, the students who live in remote areas have to come to the nearest regional study center. As a result, there is only limited interaction between students and professors in the regional centers.

Thus the major research questions were as follows:
1. Finding the factors that influence the effectiveness of a videoconferencing system(VCS): What are the instructional tendencies of the professors and interaction patterns during the distance lecturing? What are the satisfaction levels of the distance lecturing and why?
2. Management and hardware concerns: What are the technical problems to manage a VCS and how can it be improved? What kind of future vision do we need to improve VCS hardware equipment?
3. Social and cultural impact: What is the social and cultural impact of the utilization of a videoconferencing system?

2. Interactive Design of the Videoconferencing System(VCS)

From the VCS headquarters, located in Seoul, the VCS is arranged in a fashion that connects 12 regional study centers and 1 local study center. For transmission, a commercial T1(transmission speed: 1.544Mbps) communication line which is provided by the Korea Telecommunication Corporation is used.

The headquarters of KNOU established a studio equipped mainly to broadcast and lecture through VCS. Also, 7 of regional centers have the capacity to give and receive the lectures using VCS. However, the remaining 5 regional centers and 1 local center can only receive lectures since they do not have the ability to broadcast.

Hardware component

The basic hardware components can be divided into five major areas: transmission, video, audio, remote control, and support systems. For transmission a T1 class CODEC(Coder/Decoder), and MCU(Multi Channel Unit) are used. Each classroom is equipped with three color closed circuit cameras, 43" or 52" color monitors, beam projectors, VHS, VTR, and TBC that process the video signals. The audio setup includes a wireless mic system and other audio processing equipment; amplifiers, equalizers and speakers. In addition, a pentium processor PC with all the necessary software is used as the main control station; it is linked to the VTR control and Audio/Video(AV) matrix switcher. As an addional support system, a briefing system and data viewer are designed to create and support supplementary educational materials.

Finance

In 1995, KNOU was designated to be a "Distance Education Trial Institution" by the Ministry of Information and Communication. KNOU with the help of participating industries is in the processing of implementing and conducting a field study on distance education in Korea, which will be completed in 1997. Total amount of $4.325 million was invested.

Educational Scenarios

1. Support of Degree Programs
The purpose of the VCS used in degree programs is to increase interaction between instructors and students, to expand face-to-face leaning opportunities and thus to ensure the quality of distance education. For example, this system can be applied in regular lectures(schooling sessions), special programs such as a summer/winter session, or night school, as well as orientation sessions.

2. Support of Non-degree Programs
VCS can also be used to support various faculty, student, and general citizen activities as well as intra- and inter- school student symposiums, faculty meetings, and general information on education. In addition, the facilities can be leased out to other interested organizations.

3. Evaluation of the VCS

The evaluation of the VCS started in March of 1996 and completed in December of 1996; it is divided into three stages. The first stage, from March to June of '96, involved gathering information on similar cases, preliminary site visitations, the development of questionnaires, and data collection. In the second stage, from July to September of '96, site visitations were conducted, questionnaires were distributed, and interviews were performed. In the final stage of evaluation, from October to December of '96, a detailed data analysis was done. The demographics of the people in this study are the undergraduate students of KNOU, instructors, operators, and managers involved with VCS. In the course of the study, following three different research methods were adopted.

Basic Research: The review of related literature and case studies which focused on two aspects: 1. The effectiveness of VCS related programs. 2. The educational satisfaction and limitations cited concerning VCS like programs.
Field Research: Interviews were conducted and surveys were passed out to the teachers, students, and operators involved in the VCS. Through video analysis and on-site visitations, the actual teaching-learning process were observed and analyzed.
Policy Research: Forums consisting of experts in distance education were open. Through this forum, future plans for improving system stability and availability, teaching strategies, and detailed plans for increased implementation were developed.

4. Results

1. Analysis of VCS's technical aspect revealed the following points. Compared to other distance education media such as audio conferencing, VCS showed great promise and potential as the dominant distance education media. This was largely due to the fact that KNOU's VCS seemed to adequately support a true two-way interactive environment. However, in order to increase the effectiveness of VCS, more technological improvements were shown to be needed. Many technical difficulties from the source and receiving ends were cited to disrupt the VCS session. These difficulties also revealed the need for an adequate back-up transmission system other than the T1 line used for transmission. Some of the technical difficulties influenced the student's and teacher's attitude towards VCS. The unfamiliar environment coupled with these difficulties brought out some people's rejection against technology.
2. In some cases, the support tools used for the production of classroom materials burdened the teacher and was found to be a reason for an unfavorable view on VCS. Therefore, in order to increase the effectiveness of VCS, not only the direct technology involved in VCS must be improved, but also the technology that supports the classroom instructors and students should be developed.
3. Analysis of satisfaction levels and opinions of teachers and students on VCS revealed the following. Although teachers showed great satisfaction in their own teaching strategies concerning VCS, many of them commented on desire for more interaction in the classroom. There were possible reasons for this lack of interaction. However the major reason was thought to be based on the style of lecturing. In other words, the teachers were used to presenting the material in a "one-way" fashion, therefore eliminating from the start any possible interaction from the students. Interviews with the teachers revealed a high level of stress concerning the preparation of the actual lecture and material for VCS. This was viewed to be due to the unfamiliarity of environment.
4. The students generally gave a positive response to VCS, however responded that the VCS lectures were not able to bring much intellectual stimulation and reflect educational diversity. Further analysis of student feedback showed that there was much room for improvement in the operational and management practice of VCS.
5. Further analysis of the social and cultural impact of VCS revealed a favorable response

from both students and teachers. This was largely due to the new opportunities in which VCS offered. The increased availability of experts and different education media seemed to play an important role in this favorable response. Also the time factor, in which the students did not have to travel hours for a lecture, was an extremely attractive trait. This was especially true for the students who were not located near form the KNOU's main campus area.

6. Two main factors need immediate improvement when lecturing through VCS: instructor training and operator training. Instructors who did not have enough training in the VCS were observed to be uncomfortable during their whole lecture. They did not seem to form a close tie with remote students. So, training, not only for the technical use of VCS, but also for remote teaching strategies need be established. Also, many system operators who did not understand the teaching learning patterns did not cooperate effectively with the instructors in delivering the content and did not show appropriate appreciation fo the remote participants.

7. In general, students and instructors wanted more lectures through VCS. Students in the regional and local centers were satisfied because they had opportunities to access live lectures by Seoul Campus professors and hoped that this system would enable them to participate in lectures given by famous experts in various fields. Futhermore, the general public wanted VCS to expand into other general fields like adult education, and extracurricular activities.

8. Social perceptions on VCS were split, however. Where on one side, people hailed it as the next educational medium, others replied that it might be too early to make that judgement. Among these less enthusiastic supporters of VCS, many people commented that VCS was "like watching TV", "boring", and, due to the lack of actual presence of the instructor, that "they felt like they were not in the classroom." Others pointed out their frustration that their so called "classmates" in other regional sites did not "feel like their classmates" for there were few opportunities to interact with them. One of the interesting trends found in the investigation was the participants comfort with VCS largely depended on their view and understanding of the technology. If they were comfortable with and had better understanding of the technological aspect of VCS, they were more likely to adapt to VCS. However, it was interesting to note that, regardless of whether they had favorable impression of VCS or not, many people commented that VCS is appropriate for all educational subjects.

5. Discussion and Conclusion

Due to the exponential growth in telecommunications technology, many new forms of educational media have been made available over the years. One of the most attractive traits of these new distance education media is that they eliminate the spatial limitations of education. In other words, one's need to be actually present at the instructional site is eliminated. Another attractive trait is its affordability. Due to new materials and technology, using these telecommunication alternatives make education more and more affordable. Furthermore, in a world where time has become the most expensive commodity, distance education has also proved to be invaluable. No longer do people have to spend a great length of time traveling to physical locations, saving money as well.

Following the trend to establish more effective distance education media, KNOU, with the help of various corporations and the government, developed its own Videoconferencing System. Detailed evaluation has revealed that the majority of the instructors and participants have had a favorable impression of this system. However, research also revealed that there were several obstacles with respect that VCS must overcome. These obstacles can be grouped into two areas: the technological and the human aspect.

Although VCS proved to be successful in many aspects, the two way communication between instructors and participants must be further improved. Technologically, many students wished that VCS be more user-friendly and less intimidating. Sometimes even when a query was made by a participant, due to mechanical or technical difficulties, the query was lost or delayed. Both instructors and participants commented that "they weren't getting the full view" of the classroom indicating that more coordinated camera movement or monitor arrangement needs to be worked out.

This study has also revealed that if VCS is to become even more successful, proper education of VCS technology must be given not only on the participants but to the instructors as well. It has been noted that many people "sensed" that some instructors were also uncomfortable with the environment, thus, bringing down the credibility of VCS. Although technology can never replace the personal aspect of education, we believe a more personal atmosphere can be created through proper orientation and curriculum development.

VCS has shown its strengths and potential to become one of the most powerful education tools in the near future. Through this study the investigators have found that VCS is here to stay, despite its shortcomings.

Tele-Educational Services in a Future Open Service Market

ABSTRACT: Changes in the telecommunications industry are now allowing support for cooperative provisioning of multimedia tele-services. This can provide a useful model for educational organizations to handle the inherent complexity of providing tele-educational courses while leaving them time to concentrate on pedagogical issues. The Prospect project is examining the provision and management of tele-educational courses involving multiple multimedia services offered by many service providers. The paper presents the model as it applies to tele-education and presents some preliminary findings.

1. Introduction.

Internet technology is currently having a significant impact on work methods and practices as evidenced by the rise in tele-working, WWW based commercial advertising and the proliferation of commercial services offered over the internet. In distance education, email, file transfer and WWW based technologies have been used for the distribution and delivery of education material. However, up to now most web-based distance education has focused on asynchronous educational material. In these cases the course material is available on the web with e-mail or other asynchronous communication methods used for student/teacher or inter-student interaction. Given the tools available for creating such Web-based course material it is feasible for educationalists to create their own materials and to offer courses over the WWW or intranets in a relatively straightforward manner.

Unfortunately, such asynchronous approaches can only support a small subset of educational experiences. Given the need for a rich educational experience, increasing use of synchronous and mixed mode technologies are envisaged in the future. This is likely to increase significantly [Riordan 96] the amount of technologies which must be mastered in order to create a tele-educational course. It is unlikely that educators will be capable of, or even desire to master all of these technologies in addition to their own specialism. Therefore, there is a need to allow educators concentrate on the pedagogical issues. Further, it is unlikely that one technical organisation will be experts in all the technologies required to support rich educational experiences.

The Open-Service Market for telecommunications services envisaged for Europe and other world regions (the so-called Global Information Infrastructure - GII and European Information Infrastructure - EII) can significantly assist such a scenario by facilitating multiple service and (educational) content providers to cooperate in the provision of a single educational course. Such educational courses would not be limited by state or country boundaries. In addition, consumers of educational courses may have the opportunity of choosing between the offerings of multiple service providers.

The Prospect project [Wade 96] has been examining the issues which would be involved in such a marketplace. The consortium has made significant progress in specifying and implementing technology and trials of pan-European educational services and technologies. In particular, several tele-education courses have been developed which are to be offered as part of a pan-European trial of the Open-Service Market to take place in March 1997. The distance education courses have been designed to illustrate the use of different modes of teaching. This paper begins by examining the idea of an Open Service Market and the influences and opportunities such a market could bring to distance education and training. Section 3 illustrates the complexity and multi-modal nature of tele-education courses. Section 4 describes the two tele-education courses which will be offered to students as part of the Prospect trial. Finally Section 5 draws some conclusions from the work carried out to date.

2. Open Service Market for Tele-education

Traditionally telecommunications has been an area dominated by large national providers who managed their own resources and whose management technology existed as tools for their own operators, rather than being available for use by their customers. In addition as there was insufficient standardisation, there were many proprietary technologies involved. However recent developments have seen new customer requirements and deregulation of the telecommunication industry [EEC 90] result in services which have to be offered in a highly competitive environment [Wade 97]. Individual services will be designed to meet the needs of specific market sectors and customers. Customers will demand access to their own range of services independent of traditional country and network operator boundaries. This means that public services must be offered in an international manner and presented to the customers in a uniform way, i.e. a common look and feel, independent of the location of the service provider. The distinguishing characteristic of the foreseen future telecommunication service environment is the existence of several competing service providers who are forced into co-operative activities due to customer requirements such as one stop-shopping and global scope of telecommunication services. This environment is termed the *Open Service Market* (OSM).

In parallel to the development of broadband networks new multi-media end systems are being developed which enable the generation, compression, transfer and display of streams of digital video and audio. These range from low cost end systems (e.g. set top boxes or simple network terminals) up to high performance workstations. These are typical application areas where various services will be provided at different costs and with different modalities of use. The rapid development of computing and telecommunications technology affecting networks, end-systems and services are being accompanied by an opening up of telecommunications markets to greater competition. Consequently, an open market of services will develop where public and private organisations will compete in providing and using basic and value-added services. Nevertheless, significant problems in multi-media service provisioning, co-operative management, accounting, billing and security are not solved yet [Hall 96]. Constraints of the technology used in the Internet will limit its growth in terms of network capacity, multi-media services, security, customer query and control and inter-domain management.

Applying the Open Services Market to tele-education, a wide range of multimedia tele-services could be combined in several subsets to support educational teaching and instruction modes. This would allow general purpose tele-services to be provided by multiple providers. Value-added service providers would then customise and combine these tele-services to target particular markets. The Open Service Market scenario where the software environment is delivered over a computer network on each occasion of use, allows a tele-education service to be offered on a "when needed" basis and for charging to be limited to the use made of the service. Alternatively more conventional charging models are also possible [Yourdon 96]. This allows much greater scope for customisation of the service delivered to the user.

The Prospect project has chosen such a tele-educational scenario as a basis of its trial. Prospect has implemented several multimedia services (video/audio conferencing, interactive hyper media services, and Webstore) which are integrated on the desktop of teachers and students to provide what Prospect terms the Prospect Tele-Educational Environment. Each service is offered by a different service provider, with a value added service provider (tele-educational service provider) acting as the single point of contact with end customer organisations. In order to provide the connectivity required for such services, Prospect also includes a Virtual Private Network (VPN) service provider who offers network connectivity across different public (national) network operators broadband ATM networks.

As has been pointed out, Prospect is not dealing here with a conventional software application but instead with a network-delivered service. The implications of this are the existence of multiple stakeholders which must be considered fully in the design of the system. In order to trial tele-education solutions in an Open Service Market the enterprise model depicted in [fig. 1] was adopted from among a number of possible variants. This model defines the stakeholder organisations which play a part in developing and using such a tele-education service. It also identifies the roles of stakeholders and their contractual relationships.

BEST COPY AVAILABLE

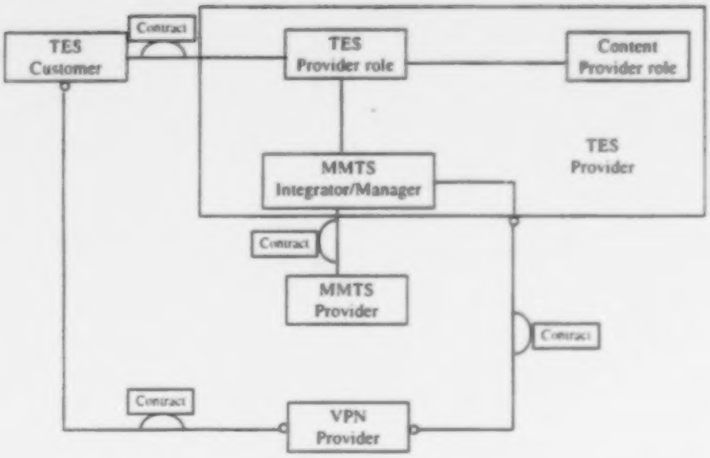

Figure 1: PROSPECT Enterprise Model

- Tele-education Service (TES) Customer - The end-user organisations of the tele-education services.
- Tele-educational Service Provider - The organisation which provides the tele-education services and who combine various multimedia tele-services along with appropriate content to support participants on a course.
- Tele-educational Content Provider - development of the educational content. This can be done by the TES provider or it can be out-sourced. The above enterprise model captures the requirements of both situations.
- Multimedia tele-service (MMTS) Integrator/Manager - will integrate tele-services and their management. This can be done by the TES provider or it can be out-sourced.
- Multimedia Tele-service (MMTS) Providers - These are the organisations which provide general purpose multimedia tele-services such as hypermedia delivery and multimedia conferencing. Their contractual relationship would be with the TES provider and not the end customer.
- Virtual Private Network (VPN) Provider - The provider of the transparent integration of bearer services (pan-European network). The VPN supports one-stop shopping and integrated billing for the network services.

3. Features of an advanced Tele-education Course

In order to illustrate how an Open-Service Market can be of benefit in the creation and operation of tele-education courses a model describing the organisation of Prospect tele-educational courses has been developed. It identifies the generic stages within a course and describes the forms of interaction between participants (tutors and students) and maps these interactions at the various stages of a tele-educational course onto possible communication/mediation mechanisms. Several forms of learning have been identified which the Prospect Teaching environment wishes to support. These learning forms are:

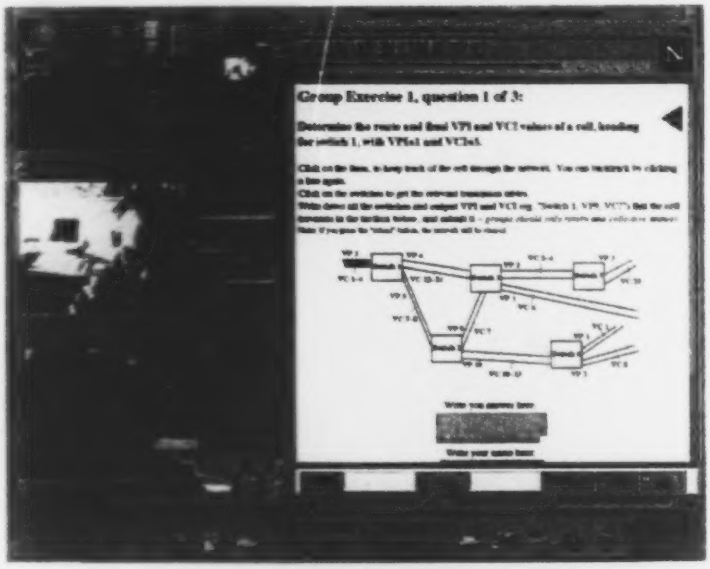
1. *Self Learning* - delivery of formatted course material for students own study.
2. *Lecture Presentation* - a one-to-many presentation by a tutor of course or organisational material.
3. *Exercises* - the facility to perform exercises either in groups or individually.
4. *Project work* - the development of sizeable projects using software outside the teaching environment.
5. *Discovery/Reference Search* - ability to locate and access background or supplemental learning material.
6. *Seminar / Class Discussion groups* - many-to-many communication between participants.
7. *Consultation* - private one-to-one communication between participants.

There is some overlap between these learning forms e.g. exercises, project work and discovery/reference search can be part of the self learning form, but all of the learning forms are listed here for completeness. To support the learning forms for the first Prospect, three partners acting as MMTS providers have implemented a multimedia tele-service each, providing both core and management services. The multimedia teleservices are briefly described as follows: *Video/audio conferencing service* - based on the MBONE tools VIC (video conferencing) and RAT (audio conferencing) [MERCI 96]. This service supports conferencing via IP multicast routers and in Prospect management of subscription to the service and accounting of the use. *Hyper media service* - allows access to be provided to hypermedia information stored on a WWW server. *Webstore service* - a managed WWW based multimedia document store, which allows users to store and retrieve arbitrary documents (text, video, audio, etc.) , using the well-known interface of the WWW. The management of the Webstore includes subscription, accounting and access control.

A mapping between the learning forms and the multimedia teleservices has resulted in a list of four basic paradigms:

Self study - individual work with web based course material including exercises and discovery/reference search. This paradigm is supported by the hypermedia and webstore services.
Lecture - teacher to class presentation supported by the conferencing and hypermedia services.
Group work - discussions, exercises or project work performed by the students in groups. This paradigm can also include shared discovery/reference search. It is supported by conferencing, hypermedia and Webstore services.
Consultation - student to tutor consultation. Supported by video/audio conferencing and hyper media services.

In order to support these four paradigms the multimedia services are integrated into a tele-educational service (TES) which provides both the core service and the management service functionality. The core tele-educational service provides two user interfaces, one for the teacher and one for the students. These integrate the underlying multimedia tele-services and add some educational specific functionality to the service, including control of which learning paradigm to use, means for the teacher to present "slides" for the students and automatic correction of small exercises in the self study module. The functionality of the service changes during a course session, according to which of the learning paradigms is used. An example of the user interface for a student doing group work can be found in [fig. 2].



Group Exercise 1, question 1 of 3:

Figure 2: Students screen during group work

BEST COPY AVAILABLE

For the management part of the integrated system two user interfaces are provided. The tele-educational service provider administrator user interface providing means to administrator subscription of the tele-educational service and accounting for its use. For the customer administrator another interface is provided to enable administration of users. Both interfaces are Java stand-alone applications. The following functions are provided:

To the tele-educational service provider administrator:

- controlling subscription of customers
- query information about subscribers, subscription contracts and service profiles
- management of users and network access points
- query information about users and network access points

To the tele-educational service customer administrator:

- management of users and network access points
- query information about users, network access points and subscription information

4. Example Tele-education Courses

Two courses are provided for the first Prospect trial, both offered by the same TES provider, but developed by two different partners acting as tele-educational content providers.

Course 1: An Introduction to ATM: The course "An Introduction to ATM" provided as part of the Prospect trials includes both synchronous and asynchronous delivery methods. The duration of the course is four days with approximately three hours of teaching and studying each day. It consist of five lectures (one each day plus a plenary discussion at the end of the course), three self study modules and three group exercises with a follow-up discussion of the results. The different modules of the course are wrapped in a tele-educational environment which also includes course outline information, a database of participants with pictures and CVs, a WWW billboard supporting off-line discussions and a tea-room which participants can "visit" for informal "chats". The lectures are performed by use of video/audio conference with use of a system to show slides on the participants web browsers. The self study modules are web pages with information to read and small built-in exercises. The group exercises consist of a number of questions to be answered by the group and thereafter returned to the teacher for correction. When the teacher has corrected the answers they are discussed in a conference with all the participants.

Course 2: An Introduction to Relational Databases and SQL: This course is designed as a self contained, self-learning course. The course is for use by a large number of students (typically about 100 to 200 students concurrently accessing the course over a one month period). The course is presented in a sequence of modules each with a specific pedagogical goal and with self assessment questions to give feedback on the students understanding and comprehension. The multimedia course material integrates textual, graphical, animation and user interactions to provide as much student participation and stimulation as possible. The tutorial style questions in each module involve the student entering both free text answers (form based) as well as multiple choice questions. As the design of the course material is modular there are several "road maps" available which support differing profiles of educational experience and bias e.g. naive user, experienced user or database programmer. The idea is to provide various navigation paths through the modules based on the different level of knowledge of student groups. A teaching support service is also provided to facilitate any user queries or problems that may arise during self study activities. The teaching support service is also involved in correcting exercises submitted on-line and in providing feedback to the students. In order to provide further stimulation of the student in the educational course, student-student and student-tutor communication is facilitated by and integrated video conferencing, audio conferencing tools. To successfully put into practice the material presented on the course, access to live commercial databases are also facilitated. Such access provides a powerful means of reinforcing the principles and techniques presented in the course. This also provides a means of allowing the student to build large project based assignments, both individually and in group projects, which provide more focused practical experience for the students.

5. Conclusions

An Open-Service Market can provide a broad range of tele-services which can then be combined to support a range of educational experiences. The Prospect project is examining how this might happen by developing service management technology and conducting trials across a pan-European ATM network. This paper illustrates two courses which are being provided during the trials. These illustrate the capabilities and versatility of the approach. A major question to be answered is how feasible is the cooperation required in model. To date Prospect has found this to be manageable given use of appropriate interface definition technologies such as CORBA. In addition the project has found that students find the learning experience very beneficial although further studies are required on this. Also participants were very happy with the flexibility offered by the courses. Problems which arise are dealing with Human-Computer Interaction issues in a multi-service provider environment and also the need for tools to support the various stages of service creation and provisioning. Lessons learned to date have been requirements for a logical structure to all course material rather than excessive use of hyperlinks, the amount of time it takes to develop the course material, the need to provide students with feedback, limit amount of content per page, provide responses to student queries in a timely manner.

Implications of Distance Education as an Agent of Sociocultural Change

Scott A. Robbins
Department of Organizational Learning and Instructional Technology
University of New Mexico
New Mexico, USA

E-mail: scar@unm.edu

Abstract: Inherent in all theories of education and training are overt schemes for the design and promotion of change. In general and at the level of surface formality, the target for change efforts is the individual learner. What is often neglected is an awareness of additional changes that may be wrought on the sociocultural fabric of the culture within which the learner is embedded. The language, content and instructional design of exported training and education programs all convey subsurface value structures characteristic of the culture of origin. This paper examines the possible effects that Western educational history and individualistic perspective may have on non-Western and non-individualistic cultures. Included are recommendations for culturally informed progress in the field.

As distance education permeates national and cultural borders, we become agents of cultural diffusion and change. The distance education literature is beginning to acknowledge the cultural implications of what we are doing in the field and the potential for sociocultural impact. To make our way through the various treatments requires an understanding of the meanings of philosophical constructs such as modernism and post-modernism, Fordism and post-Fordism, globalization, consumerism and democratization. The current literature on the cultural implications of distance education describes these concepts and forms a foundation upon which this paper is largely based (Evans, 1995; Field, 1995; Edwards, 1994; Moore, 1994). This paper synthesizes and applies what has been written on the topic and extends the boundaries of current discussion.

This paper has been structured into three parts. Part one discusses aspects of our sociocultural heritage typically overlooked in the written histories of the field. The purpose will be to illustrate the importance of recognizing our roots in the Western history of education and communications technology so we can arrive at a more complete understanding of our potential to alter culture. The second part of the paper will examine how the consideration of the specific cultural dimension of individualism - collectivism may be relevant to our theory and practice. In the final segment ideas and suggestions for developing a self-reflective, culturally sensitive and sustainable distance education model will be proposed.

The Missing History

The field of distance education is considered to be a very young and emerging sub-discipline in the larger field of education. It is not uncommon to encounter historical descriptions of distance education that begin with the description of self-study programs used in the first half of the 19th century (Moore & Kearsley, 1996). Historical accounts in the field tend to focus on the "distance" aspect which distinguishes it from traditional educational programs. An implicit assumption seems to be that practitioners and students in the field are aware of the much deeper historical and philosophical origins of education in general. This assumption has allowed those engaged in the preparation of professionals entering the field to skip or gloss over an essential historical aspect necessary to instill a more complete awareness of the potential sociocultural consequences of distance education.

Formal education has been engaged in the process of cultural reproduction, innovation and diffusion for centuries. Schools in Europe during the 15th and 16th centuries served the purpose of supplanting folk-ways of knowing and traditional networks of communal knowledge sharing. Schools introduced and promoted a new rationalism that denied legitimacy to the culture of the common people while beginning to build a cultural foundation upon which the modern nation could be constructed (Martin-Barbero, 1987). We witness, at this early stage, the ideological potential of education to support the installation of new dominant paradigms and altered cultural dynamics.

The ideological power of education can also be appreciated by examining the role of education and schooling during this century. In the United States the form and function of the public education system was influenced by a myriad of business, religious and political special interest groups (Spring, 1992). It is no accident that the public school resembles a factory in which the compliant worker-consumer is the end product. Together with the culture industry and trans-cultural corporate interests, institutional education is an essential feature of current patterns of sociocultural dominance and compliance.

Distance education is fundamentally and primarily an institutionalized form of instruction. What makes it different from traditional education is not a unique historical origin but an amplified ability to access large numbers of individuals and to transcend traditional barriers to communication. This distinguishing feature exists due to innovations in the technologies of transportation and communication. By recognizing this feature we arrive at another culturally relevant aspect of distance education, its reliance on modern forms of communications and media.

Mass media also comes to us with a historical legacy. Every technological revolution in communication has increased the power of the author, speaker or actor to gain the attention of multitudes spatially and temporally distant (Carley, 1995). Among the many cultural consequences has been the creation of a discursive space between the traditional cultures of the 'developing' world and the encroaching cultural form of the economically dominant. In a discursive process cultural norms and value structures are negotiated to the point of a compromise between the cultural demands of the traditional and those of the domineering.

The massification of culture and the increasing power of modern communication technologies have changed the way in which we conceive of ourselves and culture. Traditional cultures can be eliminated, assimilated, altered or commodified depending on the nature of the specific discourse between the target culture and the relevant embodiment of hegemony. In all cases, cultures change and individuals become compelled to redefine themselves.

By recognizing and claiming a more complete conception of our origins in education and mass communication we can begin to appreciate the importance of considering the sociocultural meanings of our decisions. By taking a deeper historical perspective we are provided with some clues as to the possible directions we might be heading. With this in mind, we now turn to examine one cultural dimension and to explore the way in which it might be effected by distance education.

Individualism - Collectivism and Distance Education

One feature that is common to all cultures is the existence of value structures. Value structures are abstract constructions that are diffused throughout cultural systems and are used by individuals to interpret behaviors. Value structures often become most obvious when they are employed to evaluate the behaviors of individuals who do not share them. Since value structures are deeply embedded within the psyches of members of particular cultures they are frequently used, in this way, without an individual's awareness. Prejudice, xenophobia and many common misunderstandings are due to the differences in value structures of interacting individuals from different cultures.

Attempts have been made to describe and compare the features of value structures of different cultures (Hofstede, 1991). The result is a growing collection of cultural dimensions that are most often correlated with nations (Smith, Dugan & Trompenaars, 1996). One commonly referenced dimension is individualism - collectivism.

An individualistic culture is one in which the individual is the focus of activity and meaning. Success in such a culture is perceived to be dependent upon the hard work and commitment of the individual to achieve. In such a culture a person's value is assigned more on their individual merit rather than any family or group connections. In the individualistic culture the individual's sense of self is largely created and maintained within their psychological structure.

Collectivistic cultures are characterized by the primacy of the group. The individual's self-identity is largely dependent upon the sense of belonging to groups which can include extended family, teams, neighborhoods or tribes. Success is more often dependent upon inter-group and interpersonal connections rather than individual achievement. In collectivistic cultures individuals are more likely to sacrifice individual self-interest if necessary to maintain harmony and promote the interests of the group.

The individualism - collectivism dichotomy can best be thought of as a continuum. All cultures have individualistic as well as collectivistic tendencies. The results of research conducted in this field are presented by arranging national cultures at various points on the continuum. National cultures which tend toward the individualistic end of the continuum include the United States, Australia and the countries of Western Europe. From Hofstede's work we find that the countries occupying the opposite range of the continuum are Latin American and Asian countries typically described as "developing" nations (Hofstede, 1991). There have been few studies conducted that give much of an indication of the position of African and Middle Eastern countries so the clustering along the continuum does not provide a comprehensive world view with regards to this particular cultural dimension.

The sociocultural contexts of the economically and technically dominant nations of North America and Western Europe represent the birthplace of distance education. As an institutional embodiment of cultural values, distance education carries the individualistic characteristics of this genealogy to an apogee. In distance education we talk of the shift of the center of the instructional transaction from the point of delivery towards the learner. The most successful distant learner is thought to be the *independent* learner who is able to tap motivational and metacognitive resources lying within themselves.

This bias of distance education toward self-motivated and independent learners has been suggested to represent a form of academic sexism in its disregard of the differences between women's and men's ways of knowing (Kirkup and von Prummer, 1990). One of the primary differences may be thought of in terms of the relative positions of men and women on the individualism - collectivism continuum. Women are thought to demonstrate differences in value structures and learning styles suggesting a greater degree of collectivism than men. Kirkup and von Prummer challenge the current conceptualization of distance learning to honor the needs of women students by expanding opportunities for social connection and interaction in the learning process. In their conclusion they state:

> *It would not be educationally justifiable to encourage these women to adopt attitudes to study similar to those of their male colleagues, but in many cases the opposite would be quite in order* (Kirkup and von Prummer, 1990).

What the Kirkup and von Prummer study demonstrates is the exclusionary potential of a distance education model that disregards the cultural differences between men and women learners. They also suggest that the practice of distance education would be improved if we paid more attention to women's ways of learning.

We can use their findings to anticipate sources of conflict and dominance that may occur with the internationalization of distance education. In thinking that distance education, as practiced in the individualistic cultures of the dominant nations, is exportable to the collectivistic cultures of the developing world we must embrace the historical ethnocentricity of our sociocultural ancestry. If we are to rise above our own ethnocentricity then we need to think and work in radically different ways.

The Challenge of Developing a Culturally Sensitive Distance Education

At this point in the development of international collaborations in distance education we are in a position to effect the nature of the new discursive space that is being created. We need to move beyond our cultural and theoretical boundaries if we hope to develop and implement models of distance education that go beyond the limits of our own history. Saba (1994) addresses the need for moving beyond the traditional unidirectional form of the international development discourse. He suggests that Systems Theory may be of some use in guiding us toward new ways of conducting intercultural distance education projects.

An essential step required for the development of an international distance education model that honors cultural differences is to seek guidance outside of our own individualistic cultures (Moore, 1994). Gayol (1994) identifies unequal partnerships and stereotypical cultural views as two constraints on the development of successful international collaborations. She points out the inherent and asymmetrical nature of power dynamics that frame international discourse around distance education. She also describes how prejudice and xenophobia come into play as we begin to interact with an "other" that is internally defined by the images presented by the mass media and racist mythology.

Ways by which the social values of cooperation and solidarity may be incorporated into a distance education program are suggested by Murillo (1994). At the Universidad Estatal a Distancia, in Costa Rica, a conscious and programmatic effort is made to counterbalance the extreme individualism manifested in distance education. The content of the materials and the structure of the educational experiences are both designed to honor the traditional values of service, personal sacrifice, cooperation and solidarity. The efforts being made in Costa Rica can provide us with models and innovative perspectives that allow us to get out of our own cultural cages and design distance education for social humans.

Conclusion

As distance educators we need to be aware of our role in changing culture and establishing the terms of an emerging global culture and to take our responsibility as agents of change very seriously. It is possible to involve ourselves in trans-cultural educational discourse in ways that honor the traditional cultures of the world. Rather than assuming that our cultural point of reference represents the ideal conceptualization of education we need to embrace the values of the cultures with which we become engaged. We have much to learn from the collectivistic cultures of the developing world. Traditionally marginalized populations within our own cultures can be better served by new forms of distance education that incorporate the wisdom of the collectivistic value structures.

From the discourse established in trans-cultural educational interactions we can support the emergence of a global culture that embodies the best of many worlds. In fact it is our obligation to do so. It is insane to think that the extension of Western habits of consumption are sustainable on a global level. There are limits to how far the consumerism of our cultures can be extended. We need to begin to consider models of distance learners outside the constraints of an individualistic paradigm.

In order to achieve culturally responsible growth in the field of Distance Education we must raise and pursue new questions in our research and practice. The following questions are some examples of places to begin a new focus of study:

- How can we facilitate two-way intercultural interaction?
- What aspects of our own sociocultural heritage are most likely to deny the values of others?
- In addition to individualism - collectivism, what other cultural dimensions may be directly or indirectly effected by the diffusion of the knowledge we present and the way in which our learners are expected to access and apply what they learn?
- What happens in culture when boundaries, norms and values are challenged by changes in the educational level and global awareness of the populace?
- What are the deeply-situated assumptions and values on which our theory and practice rest?

These questions, and certainly others, should be used to guide our self-reflection, research and practice in the field of distance education.

Phenomenology, Cognition, and the Design of Interactive Learning Environments

Wolff-Michael Roth, Lansdowne Chair
Faculty of Education, University of Victoria, Canada
E-mail: mroth@uvic.ca

Abstract: Interactive learning environments (ILEs) in education have received a lot of attention during this past decade. However, many ILE products for the educational market are little more than animated books. More so, some ILE products make it more difficult for students to access the very resources they need for learning important scientific practices. This paper argues for a different approach to the design of interactive learning environments, their human-computer interfaces, and their contents. In this approach, which is based on a phenomenological perspective of human cognition, designers begin with the worldview and discourses of future users rather than with their own conceptions of how the world looks like and works. Rather than thinking of ILE packages and their interfaces as information providers, this paper proposes to think of them as interfaces as tools and as sites for the emergence of culture through human-human interactions.

1. INTRODUCTION

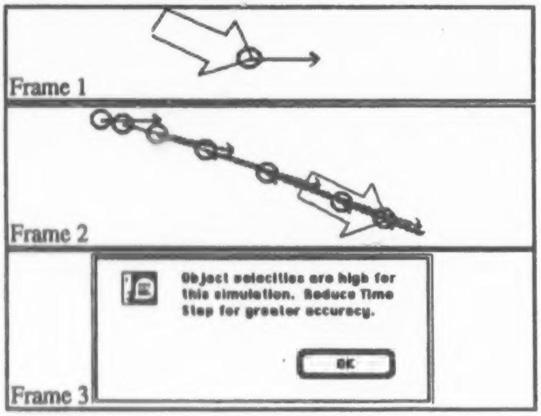
Many teachers and sales persons of ILEs stress the function of their products in terms of the information accessible. However, studies showed that even with the most sophisticated help systems, there are breakdowns in human-computer interactions that cannot be solved by users themselves (Ehn 1992, Roth Woszczyna and Smith 1996, Suchman 1987). To introduce the problematic issues, let us consider a "user-friendly" simulation program, Interactive Physics™, used in many physics classrooms around the country.

The three students in the following transcript[1] completed several assignments using a Newtonian microworld that allows users to model physical phenomena by integrating real world-like events, for example the motion of balls, and diagrams which are characteristic of canonical physics. After setting up a physical situation, a "run" button lets users observe the effect of the ball under the established conditions.

Students' present assignment asked them to explore the meaning of the arrows and provide observational and theoretical descriptions for them. Here, the three students set up (Frame 1) and ran an experiment in the microworld. After the ball raced off the screen (Frame 2), a message indicated that "Object velocities are high for this simulation. Reduce time step for greater accuracy" (Frame 3). Randy read this message almost under his breath and Linda asked for the referent of "time step" (Frame 4). First Randy then Gaalen suggested that the big arrow was time step (Frame 5).

Gaalen: OK, now run it.
Randy: Right. PUSHES RUN BUTTON
(0.8)
Gaalen: Ho:::leeee.

Baby! Yes!
Randy: [°Object velocities are high for this simulation. Reduce time
[HITS OK BUTTON



Object velocities are high for this simulation. Reduce Time Step for greater accuracy.

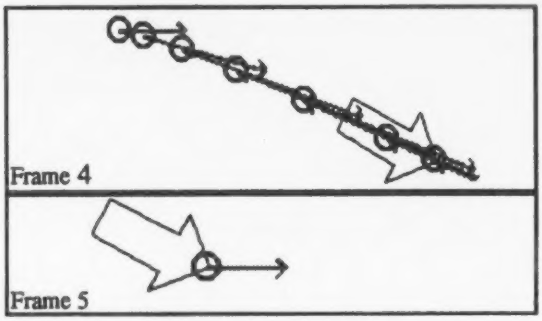
---

[1] The following transcription conventions were used: (0.8) = pauses in tenth of a second; PUSHES BUTTON = words in small caps indicate actions; ::: = lengthening of phonemes; [= indicates start of overlap with previous utterance; °object° = words and sentences between degree signs are spoken with very low volume, almost inaudible.

BEST COPY AVAILABLE

step for greater accuracy°
Linda: Which one's the time step?
Gaalen: ['K, reset
[HITS RESET BUTTON

Randy: It's that big arrow
Gaalen: Oh yeah the big arrow's time (0.9) 'K (1.4)
the big arrow's time



If the designers or the students' physics teacher had listened, they would have noticed that the students' interpretation of the big arrow was not time at all.[2] That is, students read the feedback message, but they read it in a way that was incompatible with the way the designers and other competent users of the system would read the message. It is therefore important to note that (a) the moving objects and arrows did not provide students with unambiguous information about the physics of motion and (b) the messages intended to provide users with help in their negotiation of the learning system were understood in a way that, at this point in time, impeded with learning. In this situation, the "information" was not that intended and therefore not information at all; the help system was not that intended and therefore no help at all.

Rather than viewing this interface as an information provider about physics, we can also take a tool perspective on this system. In this case, Interactive Physics™ is a tool for exploring and learning physics. As we saw, the three students did not use this tool in a transparent way. It was not *ready-to-hand* but obtruded and interfered with learning. When tools begin to interfere with our using them, they become *present-at-hand*. In the case of these three students and their peers who worked on other computer stations with the same program, there were many occasions that forced them to investigate the tool rather than the physics they were supposed to investigate and learn. That is, *breakdown* had occurred and learning did not proceed in the way intended by the teacher. Rather than learning physics, students spent a lot of time learning to handle computers, interface, and program.

Recent work on the design of human-computer interfaces suggests that the problems outlined in the above example are inherent in top-down approaches of most design (Ehn 1992, Winograd and Flores 1987). Most human-computer interfaces are not designed for breakdown but rather cause it. These and other authors suggest taking new and different approaches to the design of interactive learning and work environments; these approaches are particularly concerned with the way we experience our world and on the relationship between language and experience. They are also designed based on a different view of human cognition. To understand the nature, efficiency and rapidity of human actions, researchers now consider how intelligent behavior arises from the engagement of the individual with structures in the world: they consider the fundamental condition of any agent as *being-in-the-world*. As the hyphenation indicates, humans are considered an integral part of the situation in which they find themselves. Cognition is distributed across social, material, and historical aspects of the situation each in turn depending on the situated interpretation of the agent (Dreyfus 1991). Much of this work in cognition and learning has been influenced by Heidegger who thought of human activity in terms of shared social practices. All current social practice theories of knowing, learning and understanding take some element from the work of this philosopher. This includes the pivotal role of language in structuring our experiential world, the absence of explicit symbolic re-presentation[3] of contexts and tools during competent action, and the role of communities as resources for individuals' *concernful* actions. The purpose of this paper is to show how the work of Heidegger encourages us to change our thinking about interactive learning environments and learning at and with human-computer interfaces. Such a change in perspective gives rise to concomitant changes in the ways we (a) design interfaces and the contents of ILE products and (b) conduct research about learning in the presence of computers.

---

[2] In simulations, the calculation of the path of a moving object involves velocity and time; thus, the object moves along a straight line for a short moment, the length of the time step, and reaches a new position. Here, acceleration and hence velocity of the object are recalculated. The new velocity is used to led the object move ahead on a straight line to the new position. And so on. If the velocity or the time step are high, the calculation of the path becomes so inaccurate that the model no longer predicts the actual paths taken by moving object.

[3] Re-presentation and re-present are hyphenated to make readers constantly aware of Heidegger's (1977) fundamental point that our ideas about things are not the things themselves. The German word for re-presenting, *Vorstellen* (literally put before), connotes that the thinking person puts the contents of thought before him/herself. But it is through re-presentation that we detach ourselves from the basic mode of being and separate the knower and the known.

2. PHENOMENOLOGY OF COGNITION

The fundamental mode of existence is being-in-the-world (Heidegger 1977). That is, in most situations we do not carry around cognitive models of ourselves and the world around us, but take them for granted. Normally, we do not re-present the world in some abstract sense with objectively-specifiable aspects and properties. For example, when I want to write an article or paper, I sit down at my computer and do it. I start up the word processor and write about the phenomenology of cognition without having to think about the computer, word processor, keyboard, and so forth. I take all these for granted and focus on the piece I decided to write. Unless something goes wrong, that is, during breakdown. In cases of breakdown such as the absence or malfunction of a keyboard, we begin to actively formalize, re-present, and categorize particular parts of the world.

When we begin to formalize, re-present, and think "rationally," we do so based on our experiences, on habitual ways of seeing the world, and the present situation as it looks to us at that moment. Our world, a world that consists of objects with specifiable properties and events, only arises through involved, purposive, and goal-directed activities (Dreyfus 1991). Objects and events acquire their aspects and characteristics, that is, become "real," through our interpretations and articulations. Because articulation of the unspoken is a never-ending process, new interpretations of an object or event are always possible. These interpretations are always from within the individual's horizon that is constituted by past experiences, assumptions implicit in everyday discursive and material practices and the situation. For the interpretations of two individuals to be similar, they have to share a great deal of this horizon (Suchman 1987). The opening episode provides an example that the "objective" feedback information meant something different to students, designers, and competent teachers. Objects also emerge when the inconspicuous, unobtrusive and inoffensive nature of our everyday world and its transparency disappear. As soon as my key strokes do not give rise to the text I intended, the transparent tools are no longer transparent and draw attention to themselves. I begin to inspect the keyboard and become aware of its individual keys or if there is some other problem. Normally, I am not aware of those aspects and do not need to be. And, the aspects of which I do become aware do not have to be the same every time some problem arises, and they are inherently innumerable.

The things of our world are not what they seem to be; that is, the ontological status of things is not given a priori. The ontological status arises from naming and using things in concernful activity. We constitute the ontological character of things and their aspects by using things *in-order-to* do something. In the process of naming and interpreting, language constitutes some things and aspects; it makes manifest that about which it talks and thereby gains its significance against an unspoken but nevertheless ever present background (Heidegger 1977). The discovery of something *as* something, the emergence of structure in that which becomes visible, is a contingent achievement because naming and interpreting are functions of an individual's previous experience and goals as contingently attended.

To summarize, some of the basic assumptions underlying phenomenological thought that influence new approaches to cognition, the design of interactive learning and work environments, and ethnomethodological analyses of everyday practices are these:

- The beliefs and assumptions implicit in everyday practices are not and cannot all be made explicit and are discursively constituted for the purposes at hand.
- Practical understanding, which is observable in the spontaneous activity of people acting in their everyday worlds, is more fundamental than detached theoretical understanding.
- Our primary relationship to the world of our experience is not through having re-presentations of them.
- We are always thrown into a world shot through with meaning which is therefore fundamentally social and cannot be reduced to the meaning-giving activity of individual subjects. Social activity is the foundation of intelligibility and existence, not the individual.
- It makes little sense to speak of things that bear individual properties independently of acts of interpretation. Humans experience the world differently and therefore act in different and changing worlds. To understand someone's actions, we need to understand his/her world.
- Tools obtain two basic modes in their relation to agents: they are ready-to-hand, in which case they are employed transparently to get things done, or they are present-at-hand in which case they draw attention to themselves so that the agent no longer pursues the real goal.

3. IMPLICATIONS FOR LEARNING

Phenomenologically-oriented studies focus on student cognition during activities involving computer-based modeling software and science laboratory activities (Roth McRobbie Lucas and Boutonné 1997, Roth Woszczyna and Smith 1996). These studies confirm the outlined framework:

BEST COPY AVAILABLE

- Using the same materials, and without further teacher intervention, students observe different phenomena and develop different language to describe their observations and theories. These observations are more often different from than similar to those of canonical science. Students do not see, hear, and experience a world that scientists and teachers take for granted.
- Many tools which students are required to use in ILEs are, because of inexperience and lack of familiarity, unready-to-hand. Therefore, when students are required to conduct some activity, they frequently learn how to follow instructions, and how to operate a tool in one situation; they learn little subject matter.
- Common understandings and shared practices—using tools, seeing phenomena, describing observations—only arise from intensive interaction over longer periods of time. Canonical understandings and practices most frequently also require interactions with a person already competent in the material and discursive practices to be appropriated by students.
- The world of experience is structured in the process of pursuing relevant activity. Students constitute the ontological character of things and their aspects by using things *in-order-to* do something. When students experience continuous failure—low grades—because they do not discover the teachers' world, they will refuse to commit to learning, always waiting to find out just what the teacher wants.

Phenomenology encourages us to think about cognition in a new way: Cognition is co-extensive with *participation* in lifeforms. One learns the language of science, mathematics, and history as one learns how to play a game: By watching how others play, and by participating in, the game. The language and tools students currently have available shape their practices and limit how they interpret the world, how they act in it, and what they afford them to learn. Language and tools constitute *horizons* for our interpretive and practical actions. True learning is an uprooting process in which students fundamentally change the way they experience the world.

4. IMPLICATIONS FOR DESIGN

The phenomenological perspective outlined so far has important implications to the design of educational materials. Interactive learning environments will fail to make significant impact on learning if they do not account for the learning issues highlighted in the previous section and if they are based on the following assumptions:

- Words and sentences provide unambiguous information and instruction. ILE content and instructions are matters of information and "hard" facts. Information and facts are unequivocal and semantically independent of context and the interpretive frameworks in communities. All users read the same information in the same way.
- ILE can be made clearer and more efficient by providing more and better instructions which can overcome the misinterpretations of users.
- ILE can be self-sufficient so that students can learn individually and without interacting with peers or teacher.
- The fault in breakdowns related to ILE are the users who are computer illiterate, ill-motivated, and uninterested.
- ILE tools can be designed in such a way that they are "idiot-proof."
- Learners need to change their habits and adapt to the requirements of ILEs so that designers can maximize technological advances; technology should drive the development of learning systems and interfaces rather than users current practices.

Traditional design of human-computer interfaces and hypermedia frequently fail because there is a gulf between the ways users and designers look at the world (Suchman 1987; Winograd, 1995). What users see and read, how this shapes their future moves cannot be predicted. This was clear from the data I presented in as introduction where students made situated inferences about feedback that led them into a blind alley. What are the alternatives for designers who do not want to fall into the same old pitfalls? New breeds of designers have drawn different but not mutually exclusive implications based on the outlined phenomenological perspective on cognition. Three approaches have so far yielded improvements in the design processes of ILE and human-computer interfaces. These are ontological, usability, and participatory design.

4.1. Ontological Design

Human-computer interfaces and multimedia can be designed for breakdown. That is, ILEs and their human-computer interface have to make provisions that allow users to overcome communicative troubles between each other and with the media. An important consideration is provision for breakdown (of machines and understanding). All attempts to design for the elimination of trouble are doomed to failure: The unexpected always happens because tools and instructions are inherently flexible to interpretation (Brown and Newman 1985, Suchman 1987). It will therefore not be possible to design away all exigencies and misunderstandings. Ontological design focuses on the management of trouble, communicative and operative, and on the anticipation of breakdown.

What ILE designers must include, then, is a network of auxiliary conversations about system availability, support, training, modification, and so on (Winograd and Flores 1987); that is, ILE designers must not only produce new equipment but also encourage new languages that allow interactions to realize their potential.

The designers of the microworld presented in the introduction certainly did not design for the breakdown in understanding the feedback. The feedback was understandable to the designers and others who have experience in modeling processes. Furthermore, the learning trajectories for the students in the episode and for their peers were far too long to make the computer package feasible for student-centered instruction, unless the curricular requirements in terms of subject matter are decreased. This leads us to issue of usability and designing tools that are rapidly ready-to-hand.

4.2. Usability Design

Another important consideration must be to design ready-to-hand or transparent tools that permit users to get their jobs done without drawing attention to themselves. The success of the Macintosh user interface has been attributed to the fact that it was easily accommodated within users' current practices (among others their language) and therefore was rapidly ready-to-hand (Brown and Duguid 1992). Office personnel did not have to learn a new practice for getting rid of a file, such as "DEL path:/file" but instead put a file into a garbage can, a practice they were already used to. Usability designers explicitly take Heidegger's phenomenological approach to tools and consult on product design within the user community to see what makes them usable, that is, ready-to-hand (Whiteside Bennett and Holtzblatt 1989).

Tools are cultural artifacts that can only be understood in the context of the community that uses them. A well-designed and well-used tool therefore embodies the perspective of the community. Thus, an ILE product that aspires to teach chemistry should allow students to engage in the practices of chemists. At the same time, tools need to be capable of becoming ready-to-hand so that outsiders, who have different perspectives on the tool, can, along a rapid trajectory, appropriate the tool so that it becomes transparent to their practice. An important question then is, Does the ILE allow users to engage in the practices that are characteristic for the domain? (Winograd 1995). One of my preservice teachers recently presented a product that asks students to shoot chemical symbols from the sky. Such an ILE hardly introduces students to the practices of chemists.

The microworld in my introduction, although it was present-at-hand for the students, was a transparent tool for the teacher. This provided two advantages. First, students could learn from the teacher how the interface is used, which aspects and phenomena are relevant to canonical physics, and which descriptions are appropriate. But the teacher's talk made only sense to students after they had some experience with the microworld. Thus, through repeated interactions with the teacher, the students' practices eventually converged with those of canonical physics. Second, it allowed teacher and students to engage each other in conversations about dynamic situations at their hand. Through these conversations, students appropriated and gained experience in canonical ways of seeing and talking about the events in the microworld. Because of the teacher's facility with the tool, he could set up critical experiences appropriate for each group that helped students in learning physics.

4.3. Participatory Design

Troubles can be mediated in part if designers and future users spent a lot of time together to develop common ground, that is, common ways of seeing and talking about the things which computer environment is to accomplish. In this way, designers and users develop shared ways, tacit assumptions and common sense that assists in repairing troubles in human-machine interactions. The conception of knowing as competent participation in language and life forms has led a group of Scandinavian designers to the "participatory design" of computer-based work places (Ehn 1992). The design of intelligible computer-based workplaces requires both designers and users to speak a common language, to participate in a common form of life. That is, before Scandinavian designers could create new work places, they had to create opportunities to develop, with the future users, a common language suitable to communicate their respective interests. They achieved this by using focal artifacts that constituted sites for engaging in conversations with users. They produced mockups, prototypes, and scenarios that were modified as the common ground between participants increased. Together, designers and end users produced and participated in a new language game. Users and designers did not need to understand each other fully when they participated in design-by-doing: participation in a shared design discourse and the use of design artifacts makes constructive but different sense to users and designers (Ehn 1992). In the end, designers and users had created a set of new tools (and associated practices) that were immediately transparent in the users' world.

5. CONCLUSIONS

At present, the development of interactive learning environments is still very much driven by the worldviews of designers and their common sense understandings of knowing and learning. All too often, ILE designs are imposed on the learner rather than being designed thoroughly from learners' perspectives. The majority of products for the educational market are built on assumptions about learning that are incompatible with research on cognition. As a result these products only continue to store meaningless bits and bytes, encourage rote learning, require considerable time to be used in a transparent and ready-to-hand way. What we need is a new brand of ILE design that takes account of the way humans experience the world. What we need are products that afford the possibility for constructing coherent and recurrent conversations. Because it is often difficult to make sure that all participants talk about the same thing as they converse about conceptual issues in real time, the material presence of the object of talk through the interface must provide students with a means for coordinating just what they are talking about. The immediacy of the display must allow situated references to specific objects and the animation must afford a replay of motion by means of gestures. Through this immediacy, the interface must becomes an object of conversation immediately available. As tools, interfaces need to be designed so that they become ready-to-hand in the shortest time possible. Interface design needs to be driven by considerations of learners' current practices rather than by technological gimmicks. The core message of this paper therefore is: designers risk alienating their target community when they ignore it and when they do not make the effort of engaging with future users and conduct thorough research to find out about their perspectives and implicit understanding it.

The NICE project: Narrative, Immersive, Constructionist/ Collaborative Environments for Learning in Virtual Reality

Maria Roussos, Andrew E. Johnson, Jason Leigh
Craig R. Barnes, Christina A. Vasilakis, and Thomas G. Moher
University of Illinois at Chicago
Chicago, IL 60607
`nice@ice.eecs.uic.edu`
`http://www.ice.eecs.uic.edu/nice`

Abstract: This paper describes and discusses the NICE project, an immersive learning environment for children implemented in the CAVE and related multi-user virtual reality (VR) technologies. The NICE project provides an engaging setting where children construct and cultivate simple virtual ecosystems, collaborate via networks with other remotely-located children, and create stories from their interactions in the real and virtual world.

The NICE project is an effort to build Narrative-based, Immersive, Constructionist/Collaborative Environments for children. Developed at the Interactive Computing Environments Laboratory (ICE) and the Electronic Visualization Laboratory (EVL) of the University of Illinois at Chicago, NICE aims to create a virtual learning environment that is based on current educational theories of contructionism, narrative, and collaboration, while fostering creativity within a motivating and engaging context.

NICE is an outgrowth of two previously designed systems, CALVIN and the Graphical StoryWriter. CALVIN (Collaborative Architectural Layout Via Immersive Navigation) is a networked collaborative environment for designing architectural spaces [Leigh and Johnson, 1996]. The Graphical Storywriter [Steiner and Moher, 1994] is a shared workspace, where young children can develop and create structurally complete stories. Extracting and building on elements from these previous works, we have created a prototype learning environment for young children which presents simplified ecological models of various ecosystems within a fantasy setting.

The software is primarily designed to run in the CAVE, a multi-person, room-sized virtual reality system developed at EVL. It is, however, capable of supporting a number of different VR platforms, including simpler graphics workstations. The CAVE is a 10 x 10 x 10 ft. room constructed of three translucent walls [Cruz-Neira et al., 1993]. High resolution stereoscopic images are rear-projected onto the walls and the floor and viewed with light-weight LCD stereo glasses to mediate the stereoscopic imagery. Attached to the glasses is a location sensor. As the viewer moves within the confines of the CAVE, the correct perspective and stereo projection of the environment are updated and the user may walk around or through virtual objects. The CAVE's room-sized structure allows for multiple users to move around freely, both physically and virtually. The user interacts with the environment using "the wand", a simple tracked input device containing a joystick and 3 buttons. It is used to navigate around the virtual world, and to manipulate virtual objects within that world.

In the following sections we will explore the various aspects of our approach. Let us first describe an example of a typical session in NICE.

Description of a NICE Experience

Amy and a group of other 8-year olds wear stereoglasses and enter a CAVE. The children are represented in the virtual space by an avatar, a three-dimensional model of a character, in this case a little girl. While moving around in the space the children meet the talking signpost, one of many "intelligent" guides or "genies", which helps to direct them in the virtual world. Among the interesting spaces to explore is the garden. When they enter the vegetable garden they notice a crop growing there already. Claudio and

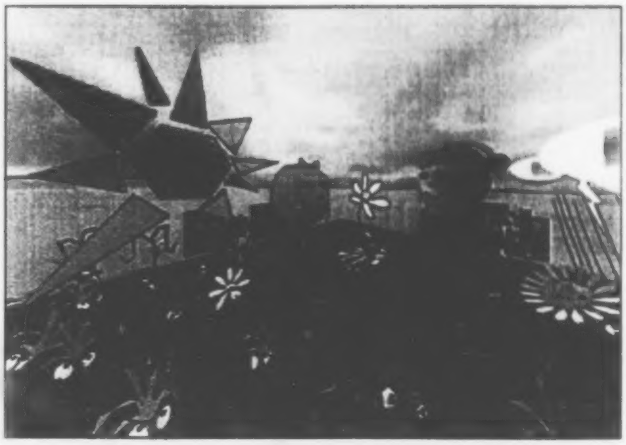

Figure 1: Children, represented by avatars, plant a NICE garden.

his friends, represented by a little boy-avatar, is waving at them. They have been planting vegetables in the same virtual garden from another, remotely-located, computer [Fig.1].

When the kids pick a seed from one of the crates and drop it on the ground, the corresponding plant, flower or tree begins to grow. The children must make sure that their plants are not too close together, and that they get enough water and sunlight. They can water the vegetables by pulling the rain cloud over them and provide sunlight by pulling over the smiling sun genie. When a plant is adequately watered, it pops up an umbrella and the children pull the cloud away; when the sunlight is too bright, the plant wears sunglasses; when it feels crowded it starts moving restlessly. The two groups of children work together to keep their garden clean and healthy. They exchange seeds and flowers, they clear out the weeds by recycling them in the compost heap, and they gather the successfully harvested vegetables in a barrel. The heavy barrel can only be lifted with the help of all remote participants and carried away from the garden. Sofia, the friendly owl genie, provides constant assistance, and the birds help with the planting.

This simple ecosystem will continue to evolve and the kids can come back and check on their progress at a later time. More children can choose characters to represent themselves, and join in from remote computers. Teachers or parents can participate, either as members of the groups, or disguised as genies. This allows teachers to advise the children in person or to direct parts of the activity from "behind the scenes". They can also predetermine the pace at which the world evolves; they may choose to see the plants grow very quickly, or, in the case of a school project, extend their growth over the period of a semester. Upon leaving the virtual environment, the children can obtain an illustrated version of their experiences in the garden they have created.

Combining Constructionism, Narrative, and Collaboration

NICE focuses on bringing together concepts of constructive group activity and narrative, within the nexus of motivation and exploration. A theoretical framework which combines the ideas of constructionism, narrative, and collaboration provides the underpinning for this environment. In the following sections we will describe the technical aspects as well as the underlying pedagogical principles of the system.

Constructionism and Exploration

Constructivism is an approach to learning that has received much attention in the educational technology circles and is being applied to many current educational software projects. Based on the learning theories of Dewey [Dewey, 1966], Piaget [Piaget, 1973], and others, constructivism deals with the ways learners assimilate knowledge by engaging in self-directed learning activities which are accomplished

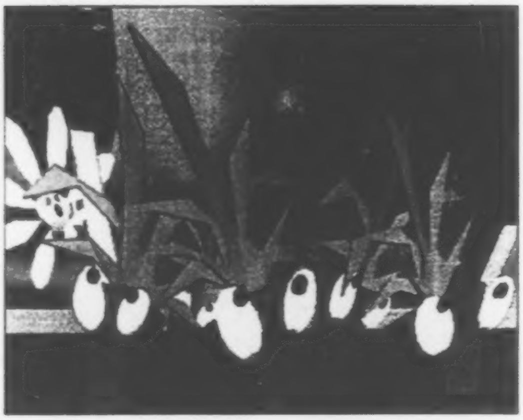

Figure 2: Becoming small in the carrot garden.

through constructive tasks. Exploration and the process of constructing objects are viewed as integral parts of these learning activities. We too believe that learning is situated in the activity of making [Brown et al., 1989], manipulating, and exploring objects, systems, and ideas. In NICE, constructive play is made possible with virtual building blocks that contain characteristics physical toys or learning tools do not: the kids can pick up heavy or large objects, hand them to other remotely located children, combine them to build new objects, or instantly observe their changing attributes over time. They can determine the environment characteristics, change their own body size [Fig. 2], disappear, fly, or leap high in the air.

All the objects, avatars and genies in the world are VRML models, which can be moved and scaled by the child in real time. The plants, trees, and flowers are simple agents with common rules of evolution and behaviour which are based on simplified ecological models. They contain a common set of characteristics that contribute to their growth, such as their age, the amount of water and sunlight they need, and their proximity to other plants. The combination of these attributes determines the health of each plant and its size. As soon as Amy drops the carrot seed on the ground, the carrot will start to grow. When she pulls the cloud over to water it, the carrot will grow faster. Visual and audio cues aid the children in determining the state of each plant or flower. The carrot will pop up a small animated umbrella to let Amy know that it doesn't require any more water. These models are handled by a central behavioural server called LIFE, which also controls the actions of the genies and story structures. LIFE can be operating constantly on any centrally located computer thus maintaining a persistant virtual world.

Narrative

Papert believes that learning takes place when engaged in the construction of a personally meaningful artifact, such as a piece of art work, a story, or an interactive computerized object [Papert, 1980]. One of the products of constructive activity in the NICE environment is the narrative, the stories formed and created by the kids that participate. The narrative revolves around the construction of the ecological microworlds and the reactions or decisions taken while interacting with the genies. Every action in the environment adds to the story that is being formed continuously, even when there is no interaction by the kids. Each child may choose to join or leave the story set at any time, while the world continues to evolve through time; the plants grow, the animals populate newly formed ecosystems or migrate to other areas, the weeds take over neglected gardens, and the flowers wilt when not watered. The narrative structure captures all of these actions in the form of simple sentences such as: "Amy pulls a cloud over her carrot patch and waters it. The tomatoes complain that they didn't get enough water. Claudio plants his first tree".

This story sequence goes through a simple parser, which replaces some of the words with their iconic representations and publishes it on a WWW page. This gives the story a picturebook look which the

Figure 3: A NICE story on the WWW.

child can print to take home [Fig. 3]. Most of the time these stories do not accomplish narrative closure, rather they come across as a series of interactions between the characters and the world. Nevertheless, the children enjoy this process, especially when they get to take home the written and illustrated version of the narrative in either printed or electronic form, or an electronic version of the scene, generated as a virtual model. The two-dimensional version of NICE also allows the children to interact with the three-dimensional VR space and create their stories through the use of Java applets on the Internet.

Collaboration

Equally important to the construction of one's knowledge is the experience gained by participation in group activity. Collaboration is emphasized in our framework through the combination of collaborative learning across both virtual, as well as physical communities. Collaboration of virtual communities refers to communication and shared experience between children who are geographically separated. The network component of NICE allows multiple networked participants at different locations to interact with each other and share the same virtual space. The representation of each tracked child in the virtual space is established through the use of an avatar with a separate head, body, and hand. As each person's head and hand are tracked, this allows the environment to transmit gestures between the participants such as the nodding of the user's head, or the waving of the user's hand to the other participants. Visually, the wand is mapped to the arm of the child's avatar. As the child waves her hand in the real world, her avatar waves its hand in the virtual world. As these avatars have sufficiently detailed representations, the children can communicate notions of relative position to one another with phrases such as "it is behind you" or "turn to your left." The use of audio (with wireless microphones) between the various sites enhances the communication process.

The number of participants is limited only by bandwidth and latency of the network. Multiple distributed NICE applications running on separate VR systems are connected via the central LIFE server to guarantee consistency across all the separate environments. The communications library uses multicasting to broadcast positional and orientation information about each child's avatar, and uses TCP/IP to broadcast state information between the participants and the behaviour system.

Collaboration in NICE may also include the interaction between the kids and the computer genies, which populate the virtual environment. The genies operate as interface and feedback mechanisms, disguised as helpful character guides that interact in the virtual world. They provide a way to replace menus and other traditional interface techniques with a more transparent and effective method for use by young children. Many times, when developing and testing the system, we use the Wizard-of-Oz prototyping technique [Wilson and Rosenberg, 1988], where actual people, disguised as genies, simulate agent behaviour. The children may be unaware of which characters in the environment are controlled by the computer and which by a human operator.

BEST COPY AVAILABLE

Collaboration also involves the social interaction among children located in the same physical space. Theories that emphasize the importance of social interaction in cognitive growth [Vygotsky, 1978] suggest that successful collaborative learning involves more than the final creation of a learning product. Learning that is contextualized in a social setting may involve verbal interaction, collective decision making, conflict resolutions, peer teaching, and other group learning situations characteristic of a classroom setting. With the use of VR technology that supports multiple users in the same physical space, as well as appropriate interaction techniques, a number of kids can participate in the learning activity at the same time, without having to take turns or wear heavy and intrusive hardware devices.

Evaluating the Virtual World

You may ask whether Amy and Claudio really need to enter a virtual environment to learn about ecology or social interaction. Wouldn't it be better if they planted a natural garden as part of a real outdoor classroom activity? Issues on the viability of VR versus traditional teaching methods are of concern to the educational world, which likes to take into account both pedagogical and practical issues.

While there are no substitutes to planting a natural garden or interacting with other children in the playground or at school, a VR environment can provide rewarding learning experiences that are difficult to obtain otherwise. As an example, ecological systems are usually complex models with many variables and behaviours that young children have difficulty visualizing. Computers can be effective at reducing the complex models into simpler qualitative representations. VR adds the qualities of immersion, direct manipulation, and exploration of such models. While in a real garden children can learn how to plant, in the virtual garden they can learn how to think about plants, scale and position parts of an ecosystem, take on different roles, become small to observe the roots, talk and interact with children at distant locations, or factor time to directly observe the effects of their changes.

However, in order to justify the educational value of the technology, effective evaluation methods need to be established to discover if conceptual learning takes place. Yet, very little has been carried out in the direction of evaluating VR environments for their educational effectiveness. In the past few months, we've observed small groups of children, 6-12 years of age, using the system, while in its various development phases. [Fig. 4]. We are particularly interested in studying the effects of VR as a learning tool, by conducting research on interface, orientation, immersion and presence, affective, cognitive, and conceptual learning issues. We have developed an evaluation framework, which takes into account the measurement of both usability as well as conceptual learning attributes of the virtual environment. With this framework we try to see through the fascination and novelty effect that surrounds this new technology and explore the actual learning experiences it has to offer. A variety of techniques are employed for gathering data, both embedded in the computer and external. The evaluation process includes the creation of a real garden by children participating in school and community-based projects, in combination with the collaborative construction of the virtual ecosystems [Roussos et al., 1996].

Although the cost and size of the CAVE, or even smaller VR technologies prohibits their use in today's classroom, it will not be long before the networked and technology-rich classroom becomes a reality. As the technology continuously decreases in cost and increases in power, more museums and cultural centers are beginning to acquire multi-user VR systems which allow for many children to participate in the experience at once.

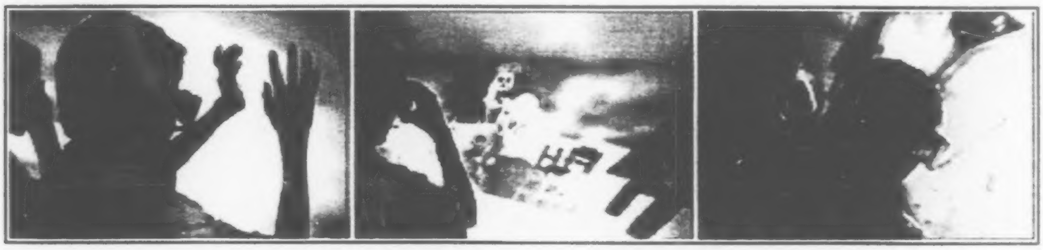

Figure 4: Children interacting with the NICE world.

Future Directions

A current goal for NICE is to further refine the interface by developing techniques for more natural modes of interaction that improve the direct manipulation of the environment and don't interfere with the learning process. Replacing the wand with a data-glove or physical gardening tools is one way of approaching the hardware interface problem. The use of many small and simple artificial guides is another improvement of the interface in the software. "Intelligent" characters can offer a clever alternative to a menu and provide direction to the children while hiding the computer.

An important addition to the present configuration is an authoring tool which will allow for user programmability of the ecosystems. This authoring tool will be in the form of a simple visual language. Visual languages have been shown to be ideal programming languages for children because they can map abstract concepts to pictorial elements that they are more familiar with [Soloway et al., 1996]. We envision a visual language where a system, as complicated as NICE, may be programmed by manipulating iconic representations of data and operators, provide immediate feedback, and can be learned quickly by the kids. Our current direction is a two-dimensional interface where the child, by clicking and draging icons to control the ecological models, can observe immediate feedback and effect in the three-dimensional VR environment.

Finally, in the direction of collaborative learning we are investigating issues of self representation and non-verbal communication. The children greatly enjoy seeing other avatars in the virtual space. One of their favorite activities is to exchange flowers and thank each other by waving, moving their heads up and down, or bowing. They also like to visualize the presence of their body in the reflecting pools in the VR world. These directions provide potential for interesting studies in gesture communication and theatrical improvisation.

Abstract. This article examines a teaching experiment in mathematics realized for fifteen years old students at Kaukajärvi School in the city of Tampere, Finland. The teaching experiment is a part of a study dealing with mathematical giftedness and development of mathematical word problem-solving skills in technology-based learning environment. In the study an empirical group comparison method was used. During the teaching experiment the group A studied problem-solving in the technology-based learning environment using SOLVER - developed for this purpose - application as a tool for learning. In producing the learning materials a contextual perspective on learning was adopted. Constructivistic, collaborative and situational views of learning were taken into account in the learning of group A. The group B studied the material with the traditional teaching methods, using paper and pencil only. A control group did not take part in the teaching experiment.

1 Introduction

The aim of this study is to examine the connection between a technology-based learning environment with the development of problem-solving skills of students at different levels of mathematical giftedness. In this study we compare the development of problem-solving skills achieved in a technology-based learning environment with learning environment of traditional paper and pencil tasks. During the teaching experiment of this study we collected data on SOLVER's suitability to develop students problem-solving skills on different levels of mathematical giftedness. [On SOLVER see Ruokamo-Saari 1996a, 1996b, 1996c.]

This study forms an independent part of the Schools to Information Superhighway (SISU) Project [see Koskelainen et al. 1996a, 1996b]. A group of mathematics teachers at Kaukajärvi School prepared problems and their model solutions for SOLVER application in cooperation with the researcher. SOLVER was produced as a part of the Näsnetti Project of Multimedia Services of Alexpress Ltd. of Aamulehti Group Ltd. The Näsnetti Network Multimedia Project belongs to The Finnish Multimedia Programme (FMP) (*http://www-tre.research.nokia.com/*). Nowadays this study is a part of Distance Learning in Multimedia-Networks project (*http://matwww.ee.tut.fi/kamu/*) of the Finnish Multimedia Programme (FMP).

This article describes the teaching experiment that was realized in the learning environment developed at the Kaukajärvi School in spring 1996. Students taking part in this study were ninth grade students. The contents of SOLVER were designed taking into account a contextual approach: word problems are connected to real life situations and thus to the real world. The solving of the problems is done collaboratively and the view of learning is "moderate" constructivistic. [cf. Ruokamo-Saari 1996a, b and c.] The theoretical background and research questions of this study has been reported earlier [see Ruokamo-Saari 1995].

2 The Methodological Solutions

The main aim of this study is to examine the connection between a technology-based learning environment and the development of problem-solving skills. In this study we compared differences in the problem-solving skills of students on different levels of mathematical giftedness - when they have been studying in different learning environments: in a technology-based learning environment and in a learning environment of traditional paper and pencil tasks. This study is experimental. The experimental group A studied in the technology-based learning environment and the experimental group B studied in the traditional way. The control group did not study problem-solving. The SOLVER application is a part of technology-based learning environment developed for this purpose. The suitability of this learning environment in the development of problem-solving skills and for the learning of mathematically gifted students was tested via the teaching experiment.

2.1 Experimental Design and the Participants of the Study

The research is an empirical and experimental comparison study of randomly chosen student groups. Experimental groups were made by lottery. The experimental design of this study is presented in Figure 1. below:

Experiment group A - MR ------ M1/A1 ------ TBLE/S1 ----- M2 /A2 ----- MM/MT ----- M3

Experiment group B MR ----- M1/A1 ---------- PP ---------- M2/A2 ----- MM/MT ----- M3

Control group MR ------ M1/A1 -------------------------M2 --------- MM/MT ----- M3

Figure 1. Experimental design of the study

In the experimental design MR (for all the groups) refers to the matrices test of Raven, M1 refers to the pretest of problem-solving skills and M2 to the posttest. A1 and A2 are tests of attitude towards mathematics, word problem-solving, computers (A1) and towards the environment used in the teaching experiment (A2). MM is a test that measures essential mathematical knowledge [Kupari 1983] and MT measures text comprehension [Linnakylä 1989]. TBLE and PP are environments - TBLE is technology-based learning environment and PP is traditional environment of paper and pencil tasks which influence the problem-solving skills we are trying to assess. [cf. Cohen and Manion 1987.] S1 for students in a technology-based learning environment denotes inquiry associated to SOLVER. M3 (for all the groups) means delayed test of lasting quality of problem-solving skills. The control group took part into the pre-, post- and delayed tests and measurements of mathematical giftedness. The purpose of these tests was to find out the differences between the students who have practiced and who have not practiced problem-solving and to find out the possible influence of pretest on posttest.

We were aware of possible consequences for students' and teachers' work when in designing of the experiment we decided to change existing grouping. Existing groups were divided so that we got three as homogenous groups as possible. Students were selected randomly. The division into the groups was made randomly so that each group consisted of 11 girls and 11 boys. In the beginning we wanted to have two times twelve students in each group, but because one computer was broken during the whole experiment, we had to make the groups smaller by taking one girl and one boy out of the groups by lot. We decided to select students randomly, this would probably not cause marked difference with matching.

Students of the technology-based learning environment group were grouped into working pairs on the basis of gender and of success in the pretest as shown in Figure 2. below:

Gi	Gi		Be	Be	
Gi	Be		Ge	Ge	(video recording 2)
Gi	Ge		Bi	Bi	
Ge	Gi		Bi	Be	
Ge	Bi	(video recording 1)	Be	Bi	
Ge	Be				

Figure 2. Student pairs made according to gender and success in pretest

Capital letters indicate the gender of the student: G for girl and B for boy. The low case letter indicates success in the pretest: letter i stands for inferior success and letter e for excellent success. We were also able to record on video all student pairs and simultaneous screens from two pairs of students while they were working.

2.2 Teaching Experiment

The teaching experiment and collecting the data lasted *11 hours*. It started at the end of the autumn term 1995 and it lasted to the end of the spring term 1996. Because in the schedule of Kaukajärvi School there was no mathematics for ninth grade students during the period January-March, we arranged six teaching lessons beginning on Friday 22nd of March 1996. A pretest was arranged before the lessons on Monday 18th of March. We collected data during the period on Friday 22nd to Friday 29th of March on consecutive math lessons, simultaneously with different groups. The first test, Standard Progressive Matrices (SPM) of Raven, was arranged on the 10th of October 1995 and last test, the delayed test, was arranged on the 15th of May 1996. The whole teaching experiment progressed stage by stage as follows:

- In the first lesson (10th of October 1995) we measured the reasoning ability of all (N=98) the ninth grade students from Kaukajärvi School with the SPM of Raven. The test lasted one hour. The test of Raven was the first part of the evaluation of students' mathematical giftedness.
- In the second lesson we arranged a pretest of students' problem-solving skills. The test lasted 45 minutes. After that we also arranged an attitude test that lasted 15 minutes. With that test we evaluated students' motivation and their attitudes towards mathematics and towards mathematical word problems and towards computers.
- The students were grouped randomly into an experiment group A (N=22) and an experiment group B (N=22) and a control group (N=22). All 66 students took part in the teaching. During the six consecutive mathematics lessons (on the 22nd, 27th and 29th) at the end of March, we collected data from student's problem-solving processes and skills and their thinking while they solved the problems. Experiment group A worked in pairs during lessons collaboratively with other student pairs.
- The posttest of students' problem-solving skills (lasting 45 minutes) was arranged after the teaching lessons (on the 3rd of April), when we also measured the attitudes of students of the experiment groups. The attitude test, lasting 15 minutes, measured students' attitudes towards learning environments and also to the experiment. On the basis of the post test we evaluated possible differences between the development of problem-solving skills of the students from the experiment and the control groups compared with pretest.
- After the posttest (on the 4th of April) we arranged two tests of mathematical giftedness; a test of mastery of core mathematics (15 minutes) and a test of text comprehension (30 minutes).
- One and a half months after the teaching lessons, on the 5th of May, we arranged the last test of the experiment, the delayed test (45 minutes). With that we tried to ascertain the stability of problem-solving skills in students, who had studied in different learning environments.

In a next chapter we describe the data collection in a more detailed way.

2.3 Measurements and the Data Collection

We collected data on mathematical giftedness with three different kinds of tests: SPM of J.C. Raven [1958] to evaluate reasoning ability, a test made of tasks of mastery of core mathematics by a P. Kupari [1983]. With this test we tried to evaluate the students' mathematical knowledge. The third test was by P. Linnakylä [1989]. With this test we tried to evaluate how ninth-grade students learn from the text. We made pre, post and delayed tests of mathematical word problem-solving to collect data of students problem-solving skills. We also made attitude and motivation tests in regard to mathematics, word-problem-solving, computers, teaching experiment and learning environment. We also collected data by recording mathematics lessons on video both in a traditional paper and pencil environment and in a technology-based learning environment. From the video material we examined the students learning processes and their interaction during the lessons. We also interviewed two student pairs, who studied in the technology-based learning environment, after the lessons using the stimulated recall-method (STRI) [Bloom 1953]. All the interviews were recorded on c-cassettes. We had recorded simultaneous screens on video from those two student pairs who studied in a technology-based learning environment, with those tapes we connected pictures from working student pairs and their computer screens. The researcher and a research assistant observed these student pairs working in real-time from TV-monitors in the class and made observations of problem-situations. The interviews were made on the basis of recorded videos and problem-situations that had been noticed during problem-solving. The interviews were carried out as soon as possible after the lessons. SOLVER saved log-files and made saving and backup files from the working of all the student pairs and their solution trees. Discussions of the student pairs via bulletin board were also saved on a server. We analyzed students' problem-solving and thinking processes and their development on the basis of these tapes, cassettes and saved files. We will also examine the effects of student pairs discussions and discussions between the students and the teacher, too - in special, how these discussions affect the problem-solving process. What kind of problem-solving processes do those girls have who did well in the pretest? What about the successful girl and the not so well successful boy? How students think about their own thinking processes has an essential role.

2.4 Analyzing Methods

In this study we analyze data using both quantitative and qualitative methods. The data comprises the scores of the tests of mathematical giftedness and the scores of the pre, post and delayed test and the scores of the motivation and attitude tests of the experiment and control groups.

The reliability of the statistical methods is dependent of the number of the cases - all in all 66 students participated in the lessons of the teaching experiment. We are, for example, able to make descriptions on the basis of frequencies and we are able to examine the connections between the variables by using correlation and crosstabulation.

We are not able to show an individual's higher or complex abilities by using only quantitative research methods [c.f. Krutetskii 1976]. We will analyze student's problem-solving processes also using qualitative techniques by observing them in different learning environments during the teaching experiment and by analyzing students' working on the basis of video tapes and cassettes that were recorded both during and after the lessons. The interviews (STRI-method) of the two student pairs after the lessons and discussions of their feelings and thinking processes, their functions and selections form the bases of the qualitative data. We are also able to analyze qualitative data from all the files saved by SOLVER and from video tapes and their simultaneous screens.

3 In Conclusion

What kind of connection there is between the learning environment and the development of problem-solving processes among students with different levels of mathematical giftedness? Unfortunately we are not able to answer this question yet. This research is at the stage of analyzing the data, which is why we are not able to give final results. It is always problematic to use experimental design: there might be some other factors in the learning environment which affect the development of the problem-solving processes that we are not immediately aware of. We have to find out the effect of these factors when analyzing the results.

This experiment was the first teaching experiment using ATM-network constructed in the Schools to Information Superhighway (SISU) Project. We had quite a lot to do with technical questions before we were able to start the experiment. Special thanks are due to the Alexpress Ltd. of Aamulehti Group Ltd. for SOLVER's technical implementation and programming and to the Digital Media Institute of Tampere University of Technology for technical support and organizing. We gratefully acknowledge the students and the teachers of the Kaukajärvi School, who were so willing to collaborate and had positive attitudes towards the experiment.

The aim of the analysis in this research is to connect qualitative and quantitative data so that they form a complementary and integrated whole. We will use the method of triangulation when analyzing the results. We have collected a large amount of data in many different forms - the analysis will still take plenty of time.

Abstract

There is a large number of authoring tools on the market for authors to chose from. Such systems usually adopt different approaches to authoring with ranging complexities. Much of the research today has focussed on how would the final multimedia application look. On the one hand, we see that such research has resulted in the development of many multimedia authoring models, databases and tools. On the other hand, there is little, or even a lack of, concern with authors and the process of authoring itself. This work looks at the problem of authoring from the authors' point of view. This process is analyzed and some guidelines, in the form of paradigm, are produced describing its main stages and characteristics. A new authoring paradigm, starting with application parametrization and going all the way to fine grained object instantiation, is proposed to overcome some of the identified problems today's authors face up.

1) Introduction

The wide spread use of multimedia tools often involves people from different walks of life including education specialists, designers, publishers, marketing and sales personal and film producers. The integration of various media has proven to be a powerful mean to facilitate communications and persuade users. It is the dynamics of media such as video and audio that makes information absorbing go beyond the mind, carrying new human dimensions such as emotions and feelings. As most multimedia users are not computer literates, we look at how easy it is for them to produce multimedia presentations under current multimedia authoring tools by analyzing the stages, components and complexity of the authoring process itself.

This paper first starts with a description of the authoring problem and its requirements. The underlying authoring model is presented. Next a quick overview of existing authoring paradigms and a comparison of these are made. Then, the proposed new paradigm is discussed. Finally, some conclusions are drawn and plans for future work are presented.

2) Authoring Paradigms - a Quick Review

Authoring refers to the process of creating anything in any area of human knowledge, generally through the help of specialized tools. Authoring should be a systematic and a well structured process. There are very few techniques specifically designed for the authoring of hypermedia documents. A great deal of these are empirical techniques [Garzotto, Paolini and Schwable 1993]. Currently there is no completely "point-and-click" authoring system; some knowledge of algorithm design and heuristic thinking is required [Siglar 1995]. As it is, authoring can be seen as an enhanced mode of programming where although the author neither has to learn a

BEST COPY AVAILABLE

programming language nor has to use a specific Application Programming Interface (API), a basic understanding of how programs work is needed.

A number of authoring paradigms can be distinguished depending on the authoring technique used. Usually a combination of one or more of the following paradigms is found.

- *Time and Flow based Iconic Representation :* At the heart of this paradigm is the use of an icon palette and a flow line. Whereas the icon palette defines all possible functions and interactions of a program, the flow line provides the way the icons are linked or arranged. This authoring style is best suited for rapid development but suffers in the way of execution since icons have different execution permutations. Examples of packages using this style of authoring are Authorware and IconAuthor.
- *The Frame Paradigm*: Similarly to the flow based paradigm, it implements a palette and links among icons. These are sometimes conceptual and do not always show the actual execution flow. It therefore offers an abstract level closer to Hypermedia. QUEST for Windows is an example of a frame based authoring package.
- *The Scripting Paradigm*: Provides a closer form to programming in that it supports an interpreted scripting language. Such a language would implement functions for the manipulation, combination and presentation of multimedia elements. These include flow control, hot-spots and links management, synchronization and presentation. Authoring systems based on this paradigm define a strong object oriented scripting language. Although the use of scripts provides support for powerful interactivity with the application environment, it nevertheless, tends to make development more time consuming. Despite the script language being interpreted, rather than compiled, the gain in terms of run-time is rather minimal when compared to other systems using different paradigms [Siglar 1995].
- *The Card Scripting Paradigm*: Combines the use of a card metaphor together with access through a script language in its user interface. This paradigm is well suited for hypertext applications and navigation intensive applications. Its main drawback, however, is the use of low performance index-card structure. Tools that adopt this paradigm include Apple's HyperCard and Toolbook from Asymetrix and Allegiant's SuperCard. HyperCard does not separate between structure definition of the hyper-document and its implementation. It adopts the "Card/Scripting" authoring paradigm. The author starts programming in the Hypertalk language!
- *The Cast Score Scripting Paradigm*: It uses a music score as its primary authoring metaphor where the synchronous elements are shown in various horizontal tracks with simultaneity (synchronization) shown in the vertical columns. Director is a widely used authoring package that follows this paradigm. Applications best suited for this style of authoring include those where animation and media synchronization are both intensive. Usually support for an object oriented language is included [Siglar 1995].
- *The Collection Paradigm*: This style of authoring allows the creation of collections which represent separate views of multimedia objects. These can be structured, in a hierarchical way, in order to support zoom-in and zoom-out operations. HM-CARD is an example of an authoring system based on this paradigm.
- ***Direct Timing Relations***: Defines timing relations to be included directly into objects and removes therefore the concept of a time and flow based line. This has the advantage of making the insertion and removal of objects a simpler task. Examples of authoring systems that implement this paradigm are Harmony [Fujikawa 1991] and the Videobook system [Ogawa and Kanedo 90a] The latter permits the grouping of scene objects into scenes which can be manipulated without having to figure out where in the time line they fit.
- *The Structure Paradigm* : Allows the structure based composition of multimedia presentations. Using this authoring technique, as described in [Rossan, Hardman and Bulterman 93a] , the author constructs a presentation in terms of two things, namely, its structure and additional synchronization constraints. The system proposed in [Rossan, Hardman and Bulterman 93a] defines two main aspects of multimedia presentation: the structure of the presentation from which based timing constraints can be derived, and the assignment of logical resources. Once the structure has been defined, the model is able to derive most of the synchronization information. Similar work has been accomplished in [Buchanan and Zelleweger 92a] . Two support views of a CMIF document are found, a hierarchical view showing the structure and a channel view showing the logical resource usage. The proposed paradigm requires a relatively greater learning curve when compared to some of simpler ones. As far as we know, there has no implementations of systems using this paradigm.

3) Discussion of Authoring Paradigms

An authoring paradigm determines the way the author undertakes authoring tasks, it therefore becomes an important component of the user interface. Due to the complexity and diversity of authoring information, a number of authoring systems have adopted different paradigms most of which have been already described.
Whereas time and flow based authoring is intuitive and best suited for rapid development, it does not capitalize on the inherent modularity of the presentation. Both time line and script based systems have this drawback and suffer in terms of execution. Fragmentation and difficult reuse of parts of the presentation are also limitations of these paradigms [Rossan, Hardman and Bulterman 93a].
The use of index-card structure makes the card scripting paradigm less attractive because of its low performance. Although the script paradigm offers a strong interactivity with the environment and better flexibility, it presents however a longer learning curve especially for authors with limited or no programming experience. Some of the paradigms are biased towards specific applications. A case in the point is the cast score paradigm which has better handling of interactive presentations and animations where synchronization is of prime importance. [Rossan, Hardman and Bulterman 93a] discusses the limitations of existing authoring paradigms and suggests a new paradigm based on structure authoring. It defines where and when objects are presented on the screen or on audio channels. Structure based authoring is far from being intuitive and requires a greater learning curve than the time and flow based one for example. Furthermore, changes to derived synchronization information is not simple to handle. Whereas card based systems are suitable for small applications, there is the risk that the author may loose track of the piles of cards and their inter-relating within an application with a high number of cards. It is the view of this work, that structure editing is the responsibility of media specific support editors rather than authoring systems. Furthermore, authors' made changes to the structure in either of the hierarchical or channel view are not simple to grasp and may have unexpected results. It is also not easy for the author to associate corresponding objects within both views. Authoring information is not always hierarchical, therefore the adoption of a hierarchical view is very limiting. The discussion above argues that none of the existing paradigms can be considered as best suited to authoring systems.
In order to avoid the limitations above and to provide support for a wide range of applications with different degrees of interaction, animation, learning curve and ease of use, the proposed solution makes use of a combination of the icon, time line, structure based paradigms and direct timing objects. This way authors may tend to use more a given combination of paradigms rather than being limited to a particular way of authoring.

4) The Authoring Model

Before, we describe the adopted paradigm, we look briefly at the ACAM model. A model offers an authoring language and makes development a structured task independent of the application. The Active Context-Based Authoring Model (ACAM) is a distributed multimedia generic authoring model. It defines four main modules for presentation, authoring, hypermedia and distribution support. The full model is described in [Kelner, Sadok and Silva 96a]. The authoring module is the object of study in this paper. It is divided into two main parts: authoring in the large and authoring in the small . Authoring in the large is the process that starts the modeling of an application at the most abstract level possible required by the author. This specification is then continuously refined until it results in one that is as close as possible to the application being presented. The advantages for such a separation include the possibility of re-using the conceptual model in the design of other applications where different refinements/extensions could be made in order to adapt this to its new application target. This is similar to the template concept used in software engineering design.

4.1) ACAM Contexts

The reader of a hypertext/hypermedia system is in charge, taking decisions in order to navigate through the contents of the islands within a hyperdocument sea. The cost of hypermedia style of retrieval is a cognitive overloading which could lead to the user loss of orientation.. This overload is a result of the fact that any piece of information could, potentially, be linked to any another one, from a different topic. There is a risk that the user or author may get lost in the hyper-space. In order to overcome this problem it would be far more appropriate to eliminate its cause, i.e. the within the authoring process in itself, through the use of a tool equipped with both an intuitive and natural information concept, referred to as context authoring .

5) ACAM's Authoring Paradigm

The aim behind the study of exiting paradigms, is to find one that supports the author in thinking in higher terms and where it is the responsibility of the system to translate the authors document into lower layer objects by automatically generating, whenever is possible, the corresponding lower level constructs.

The discussion has shown that different paradigms have different strengths and that there is no single one that outperforms all the others for all considered applications. This discussion is somehow similar to the question of which programming paradigm will dominate the future of software development. A reallistic conclusion which also confirms the current trend in programming languages would be that different paradigms would coexist at least for a while and that each one of these would have its own "niche" of applications. Similarly, in the context of authoring, a system would stand better chances of being accepted, if it successfully combines different authoring paradigms in a such a way that they appear as collaborating to enhance application semantics.

5.1) Requirements

Before presenting our solution, we look at what we hope a paradigm would achieve. In order to make the authors life easier, the retained paradigm should, in our view, observe the following requirements:

- a clear authoring process with well defined stages must be defined. Such stages should not be confined to authoring in the small (i.e direct object instantiation);
- the paradigm must avoid as much as possible the use of complex mechanisms such as scripting languages;
- simplicity intuitiveness and ease of use over power in that the user interface must be made simple by keeping the number of open windows low;
- the retained paradigm must be generic, with support for reuse and extendible;
- problem parametrization is important as the same multimedia presentations may be made available in different forms, levels of details depending on the target audience;
- support for contexts, authoring in the large and authoring in the small described earlier;
- support for media synchronization;

5.2) An Analysis of the Authoring Process

In order to support the above requirements,the ACAM user interface adopts a balanced combination of the following paradigms: time line and flow icon based paradigm, t he collection paradigm.

So far we have discussed the different paradigms and modeling techniques the proposed solution will have. Next, we describe in chronological order, which concrete authoring stages this solution defines in order to implement the proposed new paradigm. To implement the four ACAM's modeling parts, namely, conceptual, navigational, presentation and instantiation, the proposed paradigm defines seven stages that an author may execute sequentially or in a cyclic way. These are:

1. *application parametrization*: defines parameters controlling the application. Examples of these maybe the the levels of users (beginners, advanced,..) , the application purpose (education, entertainment, sales..), users age, presentation language, etc. The idea is that for each set of parameters, the same application using the same underlying model presents a different scenario. Note that this parametrization is represented by the concept of contexts earlier defined in the ACAM model;
2. *Definitions of blocks, sub-blocks and relations*: Here the application is structured in terms of blocks of information and the relations between the blocks are established. When a new block is created, the author says which context it is inserted [Fig. 1.b] in and the system can infer the navigational model. The way a

block is going to interact with another one, through the use of a selection button or after a given time has elapsed, is defined later together with the information that makes up a bloc. A user may select a bloc and define its graphics and synchronization information separately from other blocks, guarantying therefore their reuse and extendibility. They can be saved and opened separately. See [Fig. 1.a].

3. *Definition of a media library*: The user may now gather all the objects he will possibly use. These will be kept in a library and this library may be saved and reused. During the development, the author may have more then one library opened. Library objects may be real ones such as (sound, text, image, or video files) or significant names that will be instantiated later on. libraries may be continuously updated and may be stored in a multimedia database for use by other applications. An example of a library creation is shown in [Fig.1.c].

Working per block.
The author may now select one block and start working with it. See [Fig.1.d]

4. *Defining the graphics information of a block*: the author is now provided with an empty window , a graphic tool bar and the library which is always accessible. The author will build frames defining the locations of objects (except the sounds), constructing the screen structure of this block. Then he drags the desired blocks from the library and these objects will fit the pre-defined frames. As the objects are chosen the system relates them to the currently active block, and they are grouped at the bottom of this phase's window. [Fig. 1.e] shows this process.
5. *Definition of the flow and object synchronization of a block*: using this option the author may define temporal relationships among the objects of a block, through the use of a flow line to which a time scale has been incorporated, in order for these relations to be as much visible as possible. The icon "*link*" indicates that there is an interaction (as a button or a clickable object, etc.) that will deviate the flow of the presentation (represented by the left line in [Fig. 1.f] to the line below itself (the right line in the example). The deviation caused by the interaction may be from one block to another (using the icon "*block*" or among elements of the same block. It is also provided the "*rubber*" icon to control the disappearing (with or without special effects) of objects or blocks. The "*function*" icon is used for pre-stabilished functions like exit, go to another block without interaction. The elements are placed on the flow/time line according to their temporal relations and they can be stretched to visually represent their durations.
6. Test: the author may, during the authoring process test or run the entire application, or use selective testing of blocs. Any of the steps above may be repeated by the author at any time to introduce new changes.

Any of the steps above may be repeated by the author at any time to
introduce new changes;

6) Conclusions

In this paper we have presented an authoring paradigm that, unlike existing ones, focuses on the author as well as the final authoring application or product. We have shown through a comparison of some of the existing paradigms that there is no overall best paradigm, but that a suitable combination of these may produce better results. Core to this paradigm are the initial stages identified earlier, namely, the parametrization and project design phases. The proposed paradigm combines the use of icons, the time line and structured authoring. The next phase of this work is the evaluation, from users from the Visual Communications Department of The Federal University of Pernambuco of this proposed paradigm. It is hoped that their feedback will be used to improve it.

Because of the increasingly popularity and use of Internet, and trying to easy as much as possible the author's work we will also investigate the development of a high level search tool . That is, a tool devoted to look for elements (images, videos, animations, sounds, texts - not only home pages) on the Web under the input of a high level query (Ex: images and sounds related to animals). The implementation will use smart agents, which use and applications have already been under study by the other part of our multimedia and network research group, that is developing a smart agents platform [Garzotto, Paolini and Schwable 91a] over which this tool will run. The tool will be part of the authoring system helping the author on gathering the information and media objects needed to create a multimedia presentation.

Abstract: Considering hypermedia as processor ideas, we studied how twelve children play cooperatively the role of hypermedia documents authors. With this purpose, along two semesters, we developed different kinds of educational tasks supported by computers, providing children with general information about hypermedia and hypermedia tools. From weekly meetings with Windows, educational games, text and graphics editors and ToolBook authoring system, the children were became able to produce, in a collaborative way, a hypermedia document, called THE NATURAL ENVIRONMENT. In this paper, we report the study steps and analyze the children authoring process. Finally, we present the conclusions and further works.

I. INTRODUCTION

Hypermedia reproduces the human ways of storing and retrieving information by following referential links [Conklin, 1987]. Under this point-of-view, authoring and navigating processes are similar with the thinking building process. It means that new ideas are not built, one by one, in a linear fashion, beginning from nothing and concluding theirself in an established moment. Organization and representation of thinking is a process developed in many different frontages, through formulation, evidence and refutation of hypothesis, which depend and contribute in other hypothesis formulation. Understanding hypermedia as powerful idea processors, the purpose of this paper is to report and analyze how young children play the role of hypermedia documents authors.

II. HYPERMEDIA AND LEARNING PROCESS

According to Schank [1994], available educational software mimics what happens in schools. As schools everyday depends basically on didactic books, most educational software has a "page-turning architecture" [Schank, 1994]. This author understands that the "press the button for the next page" programs a very passive experience for the learners and not very educational. The reasons why this kind of software predominates in schools are related both with the lack of computing expertise and knowledge of latest theories of learning by the educational software designers. When designers have computing expertise, they do not know enough about teaching and learning techniques, reproducing current software educational models.

In spite of the large educational potentiality of hypermedia, Schank [1994] judges that it is faded to failure if they only incorporate video and figures to the traditional "page-turning programs". Consequently hypermedia programs can be either conventional tutors, or relevant cognitive tools. If the learner's presumed role is just to be a reader of hypermedia documents, it is just a conventional use with "new dressing". However, if the learner is author or co-author of the nodes and links network, hypermedia can be an important cognitive tool.

BEST COPY AVAILABLE

Midoro [1993] sees a positive educational repercussion when hypermedia allows the use of the same interface for authors and readers. Same interface could enable cooperative authoring and the development of classroom project based on the use of available educational hypermedia and on the reuse of hypermedia material for new applications. Hypermedia could still be cooperative learning tools by excellence, since it allows hypermedia documents building with shared authoring among different authors - students and teachers [Holden et alii, 1992].

Once hypermedia programs can perform as idea processors, we have been using this kind of program with school first grades learners to make them to exercise self-expression, creativity, autonomy and cooperative work, by authoring hypermedia documents.

III. CHILDREN AS COOPERATIVE AUTHORS OF HYPERMEDIA DOCUMENTS

To analyze how children play the role of hypermedia documents authors, we developed a study aiming to find answers for two questions: (1) does hypermedia documents authoring stimulate cooperative work? (2) does the diversity of media supported by hypermedia authoring systems emphasize the self-expression, improving the use of other communication channels not explored in classroom (image, sound, animation)?

The study has taken place in an elementary school where the pedagogical approach is based on the constructivist philosophy, from august/1994 to august/1995, with 8/9 years old twelve learners. In the beginning of the study, the classroom was divided in 3 groups of 4 learners. Each of these groups took a 50 minutes class per week in school computer laboratory. Flávia Santoro, first author of this paper, has acted as participant observer, guiding the computer utilization, presenting educational software and helping to solve or to minimize the conflicts.

The study first step was to introduce computers, their devices and Windows® platform to the children. To make the computational environment familiar, during four months (August/December 1994) we used eight educational games, with which the students had to solve problems together in an entertaining way. After this introduction, we searched a straightest relationship between the computer tasks and the typical classroom work in a constructivist school. All school activities are developed from thematic projects and then, we took advantage of the project proposed for the first semester of 1995 - **Natural Environment** - for introducing hypermedia authoring.

To work cooperatively with a non familiar tool - a hypermedia authoring system, we believe that children must to handle easiest and most usual computational tools. So, we firstly introduced the children in a text editor (Creative Writer®) and a graphics editor (Kid Pix®). Our purpose was to familiarize them with text and figure edition in order to start the authoring process in a hypermedia environment. They quickly learned to write texts, joining texts and figures, using the software and Windows facilities.

The children acquired some expertise in handling Creative Writer® and Kid Pix®, producing collaboratively a newspaper, with several sections (sports, general notes, jokes and games). The next step was to presented them the Asymetrix Toolbook® 1.51 authoring system. From March to July of 1995, the children learned, in a learning-by-doing approach, how to use Toolbook® and how to build cooperatively a document in a non linear way, by linking text, figures, sounds and small available animation sequences.

We chose this Toolbook® version because it allows the use of hypermedia basic resources in a simple form. Both basic concepts of hypermedia and Toolbook® were taught at the same time. Whereas they were engaged in the semester thematic project, we proposed the cooperative authoring of a hypermedia document about the chosen theme. All of the 12 children agreed and they started to build the document, that they entitled *The Natural Environment*.

III.1 AUTHORING PROCESS OF THE NATURAL ENVIRONMENT HYPERMEDIA DOCUMENT

The authoring process first stage was a meeting with the children and their classroom teacher to select the topics to be included in the hypermedia document. They selected what they wanted to study about natural environment, creating a sketch of the nodes and links network to be developed. At the same time, they learned basic notions of Toolbook®, such as nodes construction (foreground and background), text edition, sounds and figures inclusion, buttons and links between pages creation.

The twelve learners divided themselves in 6 pairs, where each pair would research and bring to classroom material about two or three topics selected by them. Each pair has made researches about the theme at home and in classroom with their teacher. Collecting material and ideas, they organized what they learned in the format of hypermedia nodes, creating the hypermedia document sketch structure. Some pairs created links between their own topics and topics chosen by other pairs. The hypermedia document first page or cover page was created by one of the groups. This group created a table of contents page, just like an index, with the titles of each topic which could be linked to the respective pages created by other pairs. Moreover, hypermedia document common elements, such as pages background color and title, were defined by other groups. Topics that had some relationship were linked by buttons and return to previous page buttons were placed in all pages as well as in index page return buttons.

Files with figures chosen by children to compose some pages were built out of the school. Children just imported figures in pre-defined format. Sounds were introduced by buttons with a script already available in Toolbook®, in which they only had to inform the name of sound file. Sounds were recorded using Windows® Recorder, generating files in WAV format.

Developing the hypermedia document, children manifested great ability in dealing with Toolbook® basic functions. In spite of all ToolBook® menus and functions were displayed in English language (in Brazil, we speak Portuguese), and its non child specific interface, the familiarity with Windows®, reached with the use of text and graphics editors, provided the necessary safety to the successful and funny task development. A high degree of motivation persisted until the end of the task in all children and the groups interest and seriousness must be emphasized. The resulting of the work was a very interesting hypermedia document, made in child typical language, available for all scholar community consult, with proposals for further continuing and increasing..

III.2 AUTHORING RESULTS: *THE NATURAL ENVIRONMENT*

The hypermedia document developed by the children has a cover page and an index page from where all other pages are called. On figure displayed on the cover page, a big button was placed, making possible for the hypermedia document readers to access the index page. Button SAIR (exit) is present in all pages, permitting to exit the hypermedia document at any time. Children has catalogued all studied subjects in the index page and the subjects theirself are buttons which takes the reader to corresponding pages. All pages called by the index page have the button ÍNDICE (index), which takes the reader back to index page. In the page "Doenças causadas pelo lixo" (Diseases caused by garbage), for example, was placed a button called "Comportamento" (Behavior), which addresses the reader to page "Comportamento".

IV. ANSWERING THE STUDY QUESTIONS

As mentioned above, we are searching answers for two main questions: "Does hypermedia document authoring process stimulate cooperative work ?" and "Does the diversity of media provided by hypermedia authoring systems (images, sounds, animation) stimulate self-expression through communication channels not explored in conventional classroom ?". Let us now report our findings.

✓ Does hypermedia document authoring process stimulate cooperative work ?

Our proposal was strongly dependent of cooperation among involved children. We could observe that authoring process supported by hypermedia has provided and improved collaboration, since every information was always accessible for all children and could be increased and grouped by each one of them. Cooperation between pairs has gradually grown up along the work. In the first classes, it was hard to keep two children in front of the computer to play together an educational game. Some time after, they are managed in producing in group and seriously the hypermedia document. This aptitude is coherent with Piaget's theory which affirms that children at this age (8/9 years old) are facing an affective and cognitive transition, overcoming an egocentric behavior to achieve a greatest socialization and the desire for sharing tasks.

✓ Does the diversity of media provided by hypermedia authoring systems (images, sounds, animation) stimulate the self-expression through communication channels not explored in conventional classroom ?

We verified that young children did not have yet the written language "vice" as exclusive way of self-expressing. Hence, when they had other available communication ways, they managed to produce material creatively using also figures, sounds, and not only written information. Non linear disposition of information seemed to be very natural for children, presenting no difficulty in building and consulting their hypermedia document.

V. CONCLUSIONS AND FUTURE WORKS

Regarding that hypermedia systems can be powerful ideas processor, we analyzed how a group of 12 children from elementary school performed hypermedia document authoring process. We verified that non-linear writing and reading, supported by hypermedia authoring system, seem to be natural to these children. We also verified that the use of other media for self-expression (such as sounds and figures) is intuitively understood as one of the manner of real world representation, not restricted to written representation.

It is interesting to observe that along the authoring process, the cooperation among children and between pairs had increased. Learner's egocentric posture in the beginning of the work (August/1994) has changed to an effective and cooperative work at the ending (August/1995). This evolution is certainly not strongly related to the use of computers - learners were passing through a transition age (8/9 years old), however hypermedia document authoring mirrored this evolution.

At the first glance, the cooperation level among the 6 pairs could have been considered little expressive, since the hypermedia document was built from an index defined by the one of the groups and the other pairs have just created their pages and made links between them. The reality is quite different: we worked with young children (8/9 years old), which plays the role of authors in a hypermedia system. Subjects choices and implementation, screen's lay-outs (commons or not commons), background colors selection, pages sequence, buttons' formats and localization's performed with low disagreement indicate good cooperation level, especially when we consider the age of our children.

Future works are directed to profound studies about cooperative authoring. The current proposal is to develop most elaborated ways of cooperative works, integrating all children of the elementary school. The thematic project selected by learners for 1996 is Brazil's History. We have already chosen topics about this theme that children are more interested, and that are, at the same time, fundamental for their learning. Now, our challenge is to promote cooperative authoring among over 50 children (7-11 years old). We are facing this challenge trying to implement different cooperative authoring levels, according to children age. But we are sure that hypermedia will help us to be successful.

The Knowledge, Skills, and Attitudes Needed in a CSCW Environment.

Steve Schlough
Communications, Education, and Training Department, University of Wisconsin-Stout, USA
E-Mail: schloughs@uwstout.edu

Abstract: The final outcome of this study was the identification of the knowledge, skills, and attitudes that are needed to effectively work in a computer supported cooperative work environment (CSCW). A list of knowledge, skills and attitudes (KSAs) was obtained through the literature search and validated through the use of a panel of experts. The KSAs were put in to a survey instrument using a Likert scale to determine the optimal KSAs of new hires who will be hired five years from now. The survey was administered by mail to a population of individuals who recruit graduates of the University of Wisconsin-Stout. The instrument was mailed to a total of 379 valid respondents and 206 useable surveys were returned for a response rate of 54%. Eighteen key KSAs were identified.

Introduction

> *It shouldn't surprise anyone that human nature, good and bad, can throw a wrench into the best-laid IT (information technology) plans, yet technocrats are constantly caught off guard by the "irrational" behavior of "end users." In fact, people who are afraid of information technology have a good reason to feel that way. Companies that ballyhoo their latest management information systems or groupware usually spend little time training employees to use them* [Davenport 1994].

[Davenport 1994] stated that many organizations spend very little time training employees. Another study also found that much of the training was not effective as it was not solving the right problem [Rosenberg 1990]. One of the ways to develop a sound educational program is through the use of a well designed and systematic task analysis [Zemke & Kramlinger 1982].

In addition to not being properly trained, an interrelated problem is that people may not be effectively using computers. Two important trends presently influencing society are the use of collaboration and use of computers. The trend toward more collaboration is expressed in the increase of work groups, work teams, group learning, and other organizational changes that require cooperative efforts among individuals, groups, and organizations [Grudin 1991] [Firdman 1991]. The increase in the use of computers has grown as the price of computers has decreased and the power of computers has increased. These two trends have blended together to create collaborative computing or computer supported cooperative work [Grudin 1991] [Firdman 1991].

One probable outcome of this technological marriage is the electronic workplace - an organization wide system that integrates information processing and communications activities. The study of such systems is part of a new multidisciplinary field:

> *Computer-Supported Cooperative Work (CSCW). Drawing on the expertise and collaboration of many specialists, including social scientists and computer scientists, CSCW looks at how groups work and seeks to discover how technology (especially computers) can help them work.* [Ellis, Gibbs & Rein 1991].

An American Imperative [Wingspread Group 1993] challenged educational organizations to define the knowledge, skills, and abilities that are expected of learners upon graduation. A study [Schlough 1996] defined those competencies for students graduating from the University of Wisconsin-Stout (UW-Stout) as they relate to CSCW. UW-Stout is comprehensive university with an enrollment of approximately 7000 students. The mission and philosophy of UW-Stout emphasize academic programs that address the evolving economic, technical, and environmental demands of a global society and that seek to integrate technology, business, and service concepts.

Methodology

The study [Schlough 1996] was conducted with its primary purpose to ascertain the knowledge, skills, and attitudes (KSAs) for an individual to be effective in a computer supported cooperative work (CSCW) environment. The objectives of this study were to develop a system to analyze the elements of job performance of a worker in a knowledge based society and to identify the knowledge, skills and attitudes needed for an individual to work effectively in a computer supported work environment. This study also attempted to answer the several research questions.

A mail survey was sent to 394 individuals who had actively recruited University of Wisconsin-Stout graduates. Two hundred and six returned the survey for a response rate of 54%. The responses were tabulated, analyzed, and the following conclusions drawn from that data [Schlough 1996].

Conclusions

It was found that there were 18 KSAs that met the decision rule. This proved that the hypothesis was valid and the null hypothesis was invalid. The KSAs that met the decision rule are as follows.

- Work in a team.
- Value team activities.
- Value continuous improvement process.
- Function as a team facilitator.
- Understand basic communications principles.
- Value diversity.
- Appreciate the benefits of empowerment.
- Use forecasting tools.
- Value the appropriate use of computer technology.
- Understand team principles.
- Function as a team leader.
- Value the capacity to adapt to change.
- Appreciate the dynamics of change.
- Understand rate of change.
- Manage change activities.
- Function as a change agent.
- Understand total quality management principles.
- Determine leadership styles.

Conclusions based on the research questions are as follows.

What is the best way to analyze knowledge based work? Although this study does not give a definitive answer on the best way to analyze knowledge based work, several observations appear apparent. The first is that a through review, analysis, and synthesis of current literature is the most important step. It was also concluded that mail and telephone surveys are a means of collecting data and validating KSA statements. These conclusions will be elaborated on in the discussion of the process.

The next three research questions: What knowledge is needed to work in a computer supported work environment?; What skills are needed to work in a computer supported work environment?; and What attitudes are needed to work in a computer supported work environment? were answered in the testing of the hypothesis. There were eighteen KSAs that met the decision rule. A more interesting finding was that the three highest rated competencies were a skill statement (work), a knowledge statement (understand), and an attitude statement (value). From this, it could concluded that, if a competency is important, it is important that an individual obtains the knowledge, skill and proper attitude required to be proficient in that competency. The top three KSAs are as follows:

- Work in a team
- Understand team principles.
- Value team activities

When reviewing the question, "Is there a difference in the knowledge, skills, and attitudes needed depending on the type and size of organization?", it was discovered that even though there was some variance among subgroups that from a practical stand point it had little bearing. When using the decision rule of a mean score of 3.75 or greater, there were eighteen KSAs that met the rule in at least one subgroup that did not appear in the composite. Of these, they all had a composite mean score of 2.96 or greater, giving them a rating of average importance or greater. The KSAs in this category were:

- Generate business letters and research reports.
- Determine personality styles.
- Send and retrieve electronic mail.
- Create charts, graphs, and flow charts.
- Create and manipulate spreadsheets.
- Create presentation materials.
- Understand basic computer hardware technology.
- Search electronic databases.

- Plan a meeting.
- Share files over a network.
- Understand basic software design.
- Use calendar/scheduling software.
- Participate in a videoconference
- Understand basic computer networking principles.
- Understand computer networks.
- Create, sort, and query a database.
- Create multimedia presentations.
- Participate in a computer based electronic meeting.

The final research question, "Will individuals require different education, training, and professional development to work in CSCW environment?", is the most difficult to draw a conclusion on. It appears that most of the KSAs that are required are within the scope of normal education, training, and professional development activities. It appears that using an evolutionary approach to adopting CSCW will allow many existing courses, resources and methods to prepare workers to perform in a CSCW environment.

Discussion of the Process

The shift in jobs to more knowledge based work has proved to be a challenge for conventional task analysis techniques. Many of competencies required in the current work place are not observable nor performed in a repetitive manner. In an attempt to meet the needs of a changing work environment, this study investigated a variety of task analysis and needs assessment techniques to create a process to predict and validate future workplace competencies.

The process used in this study began with a comprehensive literature review of needs assessment, task analysis, and CSCW. The information gathered in this literature review was analyzed and synthesized with two main objectives. The first was to develop a process to analyze knowledge, skills and attitudes needed for employment. The second was to identify KSAs needed in CSCW environment. Using fifty of the identified KSAs, an instrument was developed to test the importance of these KSAs. This instrument was reviewed by a panel of experts and appropriate changes were made. The instrument was then field tested on a group of undergraduate students with senior status and graduate students. The database of the Career Placement Office at the University of Wisconsin-Stout was queried and sorted to create a report with 394 individuals who were classified as active recruiters of university graduates. The instrument was mailed to this population. A follow-up mailing was sent to those who did not respond to the original mailing. A random sample of those who did not respond to either mailing was selected and up to five attempts were made to contact them by telephone. Those who were contacted were asked to complete a abbreviated instrument over the phone. The data was entered and analyzed. From these results, recommendations were formulated on the process, the needed KSAs for CSCW, and how workers will obtain these KSAs.

This process appears to be a legitimate way to determine KSAs, as the mail survey validated the KSAs determined from the literature review and the phone follow-up showed no practical difference in the identified KSAs, although the demographics were slightly different. Overall, the process had few weaknesses and identified KSAs that would have been difficult to uncover through observation or interview techniques. It also reinforced the premise that knowledge and attitude are as important as skills to employers.

Based on the comments received, one weakness of the process seems to be that it is difficult to solicit accurate response on emerging technologies. Several of the respondents commented that they either were not aware of the technology or did not have an in-depth enough knowledge to accurately respond. Another weakness is that even though mail and telephone surveys are considered efficient methods to collect data, both are time consuming. Suggestions on the process for knowledge based analysis will be included in the recommendations.

Discussion on the KSAs Needed in a CSCW Environment

To determine if it is important to prepare future workers to work in a computer supported cooperative work environment, the study contained two questions that asked the respondents to rate the level of importance collaborative computing plays in their organization today and if they believe it would be more important in five years. The first was, "Of what importance do you believe collaborative computing plays in organizations today?". A total of 79% of the respondents gave a rating of average importance or higher.

When asked, "What importance do believe that collaborative computing will play in organizations five years from now?", 88% responded of more importance and 8% the same level and no responses indicated of less importance. There were 4 (2%) respondents who did not answer the question. The responses to these two questions indicate that the individuals responsible for hiring University of Wisconsin-Stout graduates believe that computer supported cooperative work plays an important role in their organizations today and will play a more important role in five years. This indicates that it is necessary for graduates to possess skills related to CSCW to be successful in this environment.

The respondents were asked to rate 50 knowledge, skill, and attitude statements on level of importance and respond yes or no if they felt that current university graduates they hired possessed these skills. Of the eighteen statements that met the original decision rule to be accepted as KSA statement, on only three of these statements did more than 75% of respondents reply that they felt current graduates possessed these KSAs. The highest positive response was 84% and the lowest positive response for KSAs that meet the decision rule were 31%.

When comparing this list to a previous study [Furst-Bowe et al. 1996] conducted in 1994 at the University of Wisconsin-Stout, several recommended computer competencies were not included.. This difference may be attributed to a more stringent decision rule used by this study. The 1994 study asked if a competency was important or not. If a competency was rated as important by more than 50% or more of the respondents from two of the three samples surveyed, it was considered important by the study. These competencies were formulated into a list of recommended competencies, using a team process. The recommendations were presented to and endorsed by a variety of campus leaders. Using 1994 study [Furst-Bowe et al. 1996] as a base, it seems appropriate to consider those KSAs that produced a similar status. Those KSAs are:

- Generate business letters and research reports.
- Determine personality styles.
- Send and retrieve electronic mail.
- Create charts, graphs, and flow charts.
- Plan a meeting.
- Share files over a network.
- Understand basic software design.
- Use calendar/scheduling software.
- Participate in a videoconference.
- Create and manipulate spreadsheets.
- Create presentation materials.
- Understand basic computer hardware technology.
- Search electronic databases.
- Understand basic computer networking principles.
- Understand computer networks.
- Create, sort, and query a database.
- Create multimedia presentations.
- Participate in a computer based electronic meeting.

The factor analysis also brought out one element that was not apparent in the other analyses. When examining the results of the factor analysis, factors 2 and 3 included KSAs that had rated high, team building and change management. Factor three included general computer skills that had received slightly above average ratings. Factor 5 contained two statements that were both rated low that were more specific computer skills and in all likelihood not KSAs that would be needed by most university graduates to succeed in CSCW workplace. Factor 1 was the most intriguing factor as it contained all KSAs that related specifically to collaborative technology. These KSAs all had mean scores that rated of average importance, with a range 3.27-2.82. Even though none of the KSAs met the original criteria, they deserve special consideration as they include the KSAs that relate directly to collaborative technology. [Burleigh 1989] cautioned to be alert to emerging technologies, as they often do not meet established criteria, when collecting data because many respondents may not have a full awareness of future needs. These KSAs with their mean score are listed in Table 1.

	Statement	**Mean Score**
42	Use group project management software	3.27
45	Use a fully integrated groupware package	3.1
44	Use group decision making software	3.06
46	Participate in a videoconference	3.01
47	Participate in a computer based electronic meeting	2.96
50	Lead others in the use of collaborative technology	2.96
49	Select appropriate technology for collaboration	2.93
48	Plan a technology based collaborative event	2.82

Table 1. KSAs with highest correlation using factor loading 1

BEST COPY AVAILABLE

The data analysis, conclusions and discussion of these elements allowed the KSA statements to be explored in a variety of ways. By synthesizing, evaluating, and consolidating this information a set of recommendations was formulated, as to the KSAs needed in a CSCW work environment and how present workers and future workers may best obtain these KSAs.

Recommendations on the KSAs Needed in a CSCW Environment

The recommendations, are presented will with what was determined to be the optimal knowledge, skills, and attitudes using headings that were developed by consolidating statements and dividing them into categories focused around a theme with specific statements listed under each category. Statements in normal type met the original decision rule criteria, those in italic were rated of at least average importance and were added as part of the examination of the comparison data and/or factor analysis.

General Computing Technology
Understand basic communications principles.
Value the appropriate use of computer technology.
Generate business letters and research reports.
Create and manipulate spreadsheets.
Create presentation materials.
Send and retrieve electronic mail.
Understand basic computer hardware technology.
Create charts, graphs, and flow charts.
Search electronic databases.
Understand basic computer networking principles.
Create multimedia presentations.
Share files over a network.
Understand basic software design.
Create, sort, and query a database.

Team Building
Work in a team.
Understand team principles.
Value team activities.
Function as a team leader.
Function as a team facilitator.
Value diversity.
Appreciate the benefits of empowerment.
Determine leadership styles.
Determine personality styles.
Plan a meeting.

Change Management
Value continuous improvement process.
Value the capacity to adapt to change.
Appreciate the dynamics of change.
Understand rate of change.
Manage change activities.
Function as a change agent.
Use forecasting tools.
Understand total quality management principles.

Collaborative Technologies
Use calendar/scheduling software.
Participate in a videoconference.
Participate in a computer based electronic meeting.
Use group project management software .
Use a fully integrated groupware package.
Use group decision making software.
Lead others in the use of collaborative technology
Select appropriate technology for collaboration.
Plan a technology based collaborative event.

Examination of these competencies reveals that students have access to obtaining them through existing university experiences, if they are aware that these competencies are important and they are advised on how to obtain them. To accomplish this, a successful process that has been previously (Furst-Bowe et al. 1996) used is to make formal presentations, first to the Provost's Council at the University of Wisconsin-Stout, and then to the department chairs and program directors of each of the colleges. This process will make all major decision makers in the curriculum process aware of these competencies and the importance of them to the students of UW-Stout and their perspective employers. In addition to increasing the awareness of the need to obtain these competencies through existing experiences, it will be important to make certain that the use of these competencies is integrated into as many existing courses as possible to increase the students' potential to obtain multiple experiences relative to the KSAs needed to work in a CSCW work environment. This process should also encourage faculty to make use of collaborative technologies such as e-mail, computer based discussion groups, the World Wide Web and Lotus Notes to enhance the exchange of ideas in existing and future courses.

As the KSAs listed under collaborative technologies are not as widely used by faculty at the UW-Stout, a structured professional development activity should be developed around these KSAs and be made available to

UW-Stout faculty and staff. Even though the findings of this study were specific to UW-Stout, they should be generalizable enough that this activity would also be appropriate for other educators and members of public and private organizations. In addition, the findings of this study should be disseminated through articles and presentations.

Recommendations on the Process

The process used in this study should be appropriate to use to identify knowledge, skills, and attitudes in variety of settings were the work being performed is not readily observed. It is recommended that it is important to identify knowledge and attitudes in addition to skills, as all play an important part in today's workplace. A thorough literature review is paramount in the process to locate the KSA statements. In some situations, a literature review followed by an analysis and synthesis may be adequate. It is recommended that a mail survey be used to validate the KSA statements.

Summary

It is important to identify and update the knowledge, skills, and attitudes that individuals need to be successful in the workplace. Occupations are continually changing and educational institutions need to continually monitor those changes. This study specifically identified knowledge, skills, and attitudes that individuals need to perform in an environment were collaboration and technology are merging. It made recommendations as to specific knowledge, skills, and attitudes that graduates from the University of Wisconsin-Stout in five years should possess and recommendations on how they may best obtain them. Although these recommendations were specific to the University of Wisconsin-Stout, they should be generalizeble to a variety of settings as the responses came from a wide of array of organizations. Even though this study dealt with identifying knowledge, skills, and attitudes specifically for a computer supported work environment, the process used should be an appropriate model for analyzing competencies in a variety of settings .

Creating Collaborative Learning Environments: The Challenge for Distant Learners

Lynne Schrum
The University of Georgia
USA
Lschrum@coe.uga.edu

Abstract: Technology exists to provide collaborative distance learning and training through electronic networks and groupware, yet little is currently known about appropriate ways in which to structure these learning environments. This paper describes a research project using groupware for collaborative learning activities. The project investigated the use of groupware for collaborative writing and problem solving with undergraduate students at a military academy. A structure for choosing such software and using it appropriately is offered. Finally, results and conclusions are presented about appropriate ways to support collaborative learning using computer networks and groupware with distant learners.

Introduction

Computer networks, a common feature of business, military, and educational settings, offer tremendous opportunities for groups to communicate. It is clear that they also present a manner in which to accomplish collaborative work and enhance distant educational experiences [Rohfeld & Hiemstra 1994] Technological advances have increased the expectations for distance learning; unfortunately, collaboration and interactivity are frequently lost in new electronic environments. Groupware, a new category of software, offers possibilities to enhance traditional communication, but thus far, examination of the potential has been focused in only a few areas. The potential for distance learning is worthy of more serious investigation.

This paper will discuss the use of groupware to support collaborative distance education and create interactivity between and among groups of learners, regardless of their geographic location. It will report on ongoing research conducted with students enrolled in courses at one military service academy. The researchers investigated the benefits, problems, and serendipitous results of groups working together using new technologies and software. The paper includes a set of characteristics with which to assess software and hardware needs, and a description of the processes by which groups use this type of network application. It concludes with recommendations for using groupware to support collaborative activities, regardless of the geographic locations.

Perspectives from Literature

Traditional distance learning environments were based on correspondence through passive media (paper, audio and video broadcast) and were frequently conducted as independent experiences, with each learner corresponding only with the instructor. Recent developments in network and communication technologies have offered the opportunity to improve these environments through increased communication, interactivity among participants, and incorporation of collaborative pedagogical models.

Groupware refers to software that supports and augments group work, however, most investigations have focused on those capabilities useful in business settings, particularly among co-located populations who used the software synchronously, often in group decision activities [Valacich, Dennis, & Nunamaker, Jr., 1991]. The literature is now beginning to expand the conceptualization of the use of groupware to include asynchronous and geographically distant activities.

It has become clear that technology has the potential to change the way in which people behave, according to Lea and Spears [1991]. They identified a change in informal and formal talk, and individuals' loss of identity and de-individuation. Tatar, Foster and Bobrow [1991] suggest consideration for what group work really means. It is not just individuals working at computers at the same time, but it means "giving participants the ability to judge when it is appropriate to overlap, just as they judge the efficacy" of adding to verbal conversations [1991, p. 77]. It is necessary that group members learn and act out their roles in these situations [Olson & Bly, 1991].

Learners report greater control and responsibility toward their learning; students also find that the act of writing demands greater reflection than speaking [Harasim, 1990; Rohfeld & Hiemstra, 1994]. Several research and anecdotal studies have looked at online components of traditional courses and have concluded that these components substantially increase the communication between the teacher and the students, and among the students, when compared with similar writing classes without the computer communication component [Hartman, Neuwirth, Kiesler, Sproull, Cochran, Palmquist, & Zubrow, 1994; Hiltz, 1990; Schrum, 1995a].

Regardless of the medium, electronic communication appears to foster collaboration and group interactions. In a study of distributed research, in which individuals who were geographically distant from each other collaborated on a research project, Olson and Bly [1991] concluded that

> interpersonal computing supports people communicating and working together through the computer; it includes tools to support interaction separated by time and/or space as well as face-to-face interaction and meetings. ... Work forced the boundaries of social place to extend beyond the boundaries of physical place. [p. 81]

Recent research on groupware suggests that, in using tools such as hypertext, "aspects of group 'process' have become tightly integrated in (if not inseparable from) the resulting 'product' of the group" [Oravec, 1996, p. 80]. In a study of group activity, Olson and Olson [1996] compared controlled activities for groups using groupware and those meeting face to face. They examined three outcomes, satisfaction, quality and process, and report that those using the groupware were less satisfied, remarked on the lack of group interaction, and yet the quality was higher in the computer groups.

Leadership is also an important issue in using groupware, especially in the context of this research. Recent studies suggest that typical leadership styles may not work in the same manner in a networked environment, as Oravec summarized,

> Effectiveness of various leadership styles may differ with group characters; for example, charisma may be critical in leading a spontaneous, real-time brainstorming session but other, less flamboyant styles may be more effective when detailed backstage planning and consensus building are required. [p. 81]

Many questions remain unanswered about the use of groupware and networks for learning collaboratively, and perhaps it is insignificant whether the participants are geographically separated or co-located. For the purposes of this study, we chose to begin with co-located learners, to have better control over the environment and to monitor the hardware and software.

Research Design and Methods

These research projects were created to determine the viability of using groupware to support collaborative writing and problem solving within the context of already planned and assigned projects within courses that meet in a traditional face to face model. A military service academy represented a unique opportunity to study such uses, because all participants had access to high end technology. In addition, group projects are frequent yet most cadets have reported disliking them, possibly because they rarely have the possibility to work together on group projects. Researchers recruited the professor of a summer class to participate in the pilot projects.

After study of many groupware packages, researchers and personnel at the Service Academy determined that LotusNotes would be the most desirable choice for the various experiments. Once this decision was made, effort was expended to create scenarios and job tools, and ascertain hardware requirements for successful implementation.

Methods

Methods that were planned included Likert type pre- and post-test surveys of all participating students, electronic and on-site observations, semi-structured interviews with randomly selected participants and the instructor, and analysis of transcripts of group process work. Data analysis included statistical analysis of the pre- and post-tests, content analysis of the observations, interviews and transcripts of group processes. The qualitative data were coded by the researchers individually and then the researchers compared and synthesized the results. The utilization of multiple methods and peer interaction was designed to triangulate the research perspectives and increase the understanding of the participants' perspectives and response to the activities using groupware.

A case study approach is also an appropriate manner in which to investigate this type of emerging phenomenon, particularly in a situation that is evolving and in which it is important to ascertain the participants' understandings of the processes. Qualitative methods "are a source of well-grounded, rich descriptions and explanations of processes occurring in local contexts" [Miles & Huberman, 1984, p. 15]. This course represented a challenge for traditional research methods, especially considering that conducting research using ethnographic techniques via an electronic format is a fairly recent possibility; to do so in an ethical manner is an even greater challenge [Schrum, 1995b].

Efforts were expended to triangulate the data sources and methods, and to include all possible opportunities to understand the experiences from as many perspectives as possible; these included analysis of written documents and group discussions, individual perspectives, and community memories [Lincoln & Guba, 1985; Miles & Huberman, 1984]. The text exchanges, lessons, and responses were captured for analysis. Individuals were invited to participate in individual electronic or telephone interviews that were designed to investigate the program processes, document variations among and between participants, and sought to understand and describe the events and resulting impacts from this course. These semi-structured interviews were conducted using naturalistic inquiry. The qualitative data were coded by the researcher and then compared, analyzed, and synthesized based on emerging themes.

Additionally, an evaluation survey was conducted using Likert-type scales and allowing anonymous responses. Respondents were asked to indicate their agreement on each statement across four options. These evaluation surveys were computed for means and percentages to understand participants' responses to the conferencing software, the study guides, and the online communication experiences. Descriptive data were also collected from the participants.

The questions with which we began these research investigations included:
What were the pedagogical strengths and weaknesses in this environment?
What benefits and difficulties did participants report when using groupware for collaborative writing?
What incidental or serendipitous learning occurred while using groupware for collaborative learning?

Research Projects

Project Alpha Description

The class, a mandatory course focused on leadership, had twelve students. These students were enrolled during the summer primarily to reduce their fall semester load, for either sports or flight activities. The class met 15 times, for three hours per meeting. These students were all comfortable with computers, with electronic communications, and with group projects, however none of the 12 had previously used groupware.

The first pilot consisted of students entering a networked computer lab, but having no previous information about their intended activity. They were given a brief introduction to LotusNotes. Then they were randomly assigned to groups of four and were given three hours in which to collaboratively write a paper describing a policy decision that was unpopular and ways in which leadership might respond to this circumstance.

During this pilot the students were given three hours in which to complete the task. Unfortunately, the hardware and software posed enormous problems for the students. Computers crashed, the software refused to allow printing, and in total the perception of the groupware was largely negative. In spite of these difficulties, the groups did produce a collaborative paper, and managed to complete the assignment on time.

Project Bravo Description

The twelve students were divided into three groups of four students each by the instructor. Their task was to visit an organization in the local area, either a business or other enterprise, identify its organizational culture and leadership patterns, and then to collaboratively write about their experience. They were to assess the situation as they saw it, and to analyze the organization with respect to the leadership attributes they had studied. They were again asked to use LotusNotes in the networked computer lab to complete this project, and they again had three hours in which to accomplish this. One of the groups completed this task on one day and the other two groups completed this task on a separate day.

Results

Unfortunately, the researchers feel that the difficulties encountered severely compromised much of the statistical data. Given the difficulties with the hardware and software, and the artificial nature of the assignments, expectations were not extremely high. Nevertheless, data were generated and information was gathered that proved important and informed the planning for the next set of projects. Many things became clear during these pilots.

Overall, an electronic network did enable collaborative and group activities. Interaction was fostered and students were individually, responsible and accountable for that interaction, and for the ultimate product. Strategies to accomplish the tasks were identifiable.

Group Dynamics and Process

Leadership patterns and roles emerged although it is unclear how the nature of the task impacted these roles. Each group began its assignments with a flurry of messaging, which tended to promote a "division of labor" collaborative writing model, and a good deal of humor. The initial activity appeared to be an organizational phase, in which they all participated. Some volunteered for tasks ("I'll do the body") and other tasks were assigned by skills, for example, one cadet was assigned the task of "turning it into English." After they brainstormed and designed their strategies, it was clear that they then individually worked to actually gather resources and begin their writing tasks.

Technical Difficulties

From the observations, interview comments, and transcripts, it was clear that the students felt that they could have more easily accomplished the task without using the network and groupware, or could have used the network with electronic mail and attachments. They also felt that even if the technology had worked perfectly it would not have been better than their traditional manner of group work. The reality of the situation (participants sitting in one room with multiple researchers observing them) and the artificial nature of their task (to accomplish something using technology that would have been easier done by talking) was disconcerting.

Yet, despite the difficulties, the groups reacted with enormous patience, even during 30 minute computer downtimes. They were not concerned that their deadlines were fast approaching, and the system was worthless, or that they could not print their report. A few individuals did show signs of stress and frustration (slamming a mouse on the desk, demonstrating symptoms of discomfort, or being off task). For the most part, however, adaptive behaviors dominated. They reverted to their word processing and electronic mail systems, when all else failed.

From these pilots and other investigations, it is also clear that tasks given to learners must be relevant and authentic. Imposing quiet on the participants would have assisted with the experiment, but would have been difficult and increased the artificial nature of the task, not to mention that this may have interfered with their learning. Equally onerous for the students was the researchers' use of video cameras; this was mentioned by all those who were individually interviewed.

Beyond the nature of the task, a great deal was learned about the planning and support necessary for actually carrying out a project using groupware. First, technical support is essential. All components of the technology must be running smoothly, operationally sound, and those hardware glitches that can be identified as potential hazards must be resolved. Choosing a software package that can accomplish necessary tasks, given the nature of the learning

BEST COPY AVAILABLE

experience, and yet not overwhelm the participants and support system is a delicate balance. Additionally, sufficient time must be allowed for learning and experimenting with the groupware.

Second, it is clear that all personnel have a stake in the success of the project. This ownership of the project is essential if individuals are expected to learn new skills, to provide timely assistance, and to tackle difficult problems. Third, it would be extremely helpful to determine which participant prerequisites (for example, knowledge and skills of computer applications) are significant to the success of the activity.

Putting together lessons from these experiences, the literature and other communications [Barrows, 1995; M. Guzdial, 1997, personal communication) the researchers began to identify support structures for geographically separated learners. It became clear that some activities are logically completed collaboratively (brainstorming, identifying the problem, choosing the place to begin, designing a solution, and testing out that solution) and others for which groupware and collaboration are not particularly useful (constructing and writing documents). Those creating such projects would be wise to structure activities with organizers and frameworks that encourage learners to explore ways in which the tools actually enhance their work. Giving learners control and support for self-determination of appropriate uses will accomplish the goals more successfully.

Conclusions

Distance education represents a step toward lifelong learning so individuals can maintain professional expertise, share information, and work collaboratively. Technology can support these goals with interactive networks and groupware, which allows synchronous and asynchronous discussions, collaborative activities, and group decision making. This research looked carefully at the emerging phenomenon of online and collaborative learning.

These research efforts represent a first step at investigating the use of groupware for collaborative learning experiences. This paper described one distance education course, delivered using an Internet and web based groupware product, from the perspectives of the students and instructor. It also provided information about the viability of groupware for collaboration within a single course setting to accomplish new activities, and identified activities that are inherently best done as a group and others that are more easily and appropriately accomplished individually.

These studies demonstrate that groupware holds potential for interactive collaborative learning, and distance education for many activities, but is not completely successful for all learners in all situations. The researchers, using information from this and other studies, created a framework to identify applications of groupware, which include education, business, and research.

Lessons learned from these experiences have informed planning for using groupware, and assist instructors in creating viable courses and assignments for both teaching and learning. Results suggest positive outcomes for content learning, and some strong suggestions for improving the structure and process of this type of online activity. Further research is needed to provide more information regarding best practices in using groupware for content specific learning, collaborative problem solving, and group processes.

Challenge-Driven Learning:
A Model for Children's Multimedia Mathematics Learning Environments

Kamran Sedighian
Department of Computer Science
The University of British Columbia, Canada
E-Mail: kamran@cs.ubc.ca

Abstract: Many children have difficulty learning mathematical subjects and are not motivated to study mathematics. To make learning mathematics an enjoyable activity for children, this paper proposes the use of a certain model for designing multimedia mathematics learning environments. In this model, learning of mathematics is a dialectic process between challenge and knowledge building. One implementation of this model is presented, and the preliminary results of a study that was conducted using this implementation are presented. The results indicate that this model can help educators design learning environments which can be very effective in helping children learn and enjoy mathematics.

Introduction and Background

Many children find learning mathematics difficult, irrelevant to their lives, and boring. This paper presents a model of multimedia mathematics learning environments, focusing on the dynamics between challenge and learning, that addresses this problem.

The difficulty in helping children to learn mathematics is twofold: 1) to motivate them to want to spend time and engage in mathematical activities, and 2) to aid them cognitively to construct mathematical knowledge.

Electronic games are an integral part of the social life of children [see Provenzo, 1991]. Well-designed mathematical computer games can meet some of the psychological needs of children and motivate them to want to learn mathematical subjects [see Sedighian & Sedighian, 1996]. Malone [Malone, 1981] studied children's fascination for non-educational electronic games to find out what makes these games fun and enjoyable. He found that electronic games had certain features in common: they provided a feeling of control in children, they made children curious, they provided both intrinsic and extrinsic fantasies, and they challenged children. Based on these and follow-up studies, Lepper and Malone [Lepper & Malone, 1987] suggested the use of computer games as possible means for instructional activities.

On a broader conceptual level, since the 1960s, Csikszentmihalyi and his colleagues [Csikszentmihalyi, 1975; Csikszentmihalyi & Csikszentmihalyi, 1988] have been studying the nature of happiness, joy, anxiety, and boredom. In their theoretical model of enjoyment, they describe *flow*, an intrinsically motivating and rewarding state in which an individual derives optimal experience from an activity. "Games are obvious flow activities, and play is the flow experience *par excellence*. Yet playing a game does not guarantee that one is experiencing flow, . . ." [Csikszentmihalyi, 1975, p. 37]. Flow activities have certain structural characteristics [*ibid.*; Norman, 1993]. One of these characteristics is a balance between challenge and skill. Csikszentmihalyi [1988] states that "optimal experience requires a balance between the challenge perceived in a given situation and the skills a person brings to it. . . . To remain in flow, one must increase the complexity of the activity by developing new skills and taking on new challenges. . . . Flow forces people to stretch themselves, to always take on another challenge, to improve on their abilities" (p. 30).

One of the most challenging tasks in producing a sustainable, intrinsically motivating activity is to keep the ratio between a person's capabilities and encountered challenge within a range which results in neither boredom and lack of fun nor worry and anxiety. When the challenge is greater than one's capabilities, one experiences worry and frustration; when one's skill is greater than the challenge, one experiences boredom [Csikszentmihalyi, 1975, p. 49]. Csikszentmihalyi [Csikszentmihalyi, 1988] suggests that one of the urgent applications of the flow theory is in education. Before presenting an application of this theory, however, it is important to consider some of the cognitive aspects of learning.

As stated before, mathematical computer games can engage children in mathematical activities. However, such engagement, by itself, is not enough to fulfill the learning and instructional needs of children. Insightful learning requires conscious reflection upon one's performance and problem solving [for example, see Van Lehn, 1991; Klahr & Dunbar, 1988]. Norman [Norman, 1993] emphasizes and discusses at length the importance of reflective cognition in meaningful learning, and laments that the current state of educational technology indicates its ignorance of this cognitive issue. Most educational games do not force children to reflect on the underlying mathematical concepts and consciously and thoughtfully react to the mathematical challenges that arise in the game. Reflective cognition is hard work, and if a tool is not designed properly, it can cause frustration and lack of interest in learning, and in some cases even repulsion. "Multimedia for education must minimize the fluff and get the users working -- working hard, not because they have to but because they want to" [*ibid.*, p. 41].

A fundamental question to be addressed is: How should a learning artifact be designed so that it actively promotes reflective thought while not compromising the characteristics of a flow activity? In the following section, a model of such a system is briefly presented. This model combines and integrates the aforementioned ideas and applies them to a multimedia mathematics learning environment. Afterwards, one implementation of this model -- *Super Tangrams* (*ST*) -- is presented, and the results of a study that was conducted using *ST* are reported.

The Model

In the flow model challenge and skill are generic parameters. When these parameters are mapped to a mathematics learning environment, challenge and skill respectively become: required mathematical capability, and newly constructed or acquired mathematical knowledge. Keeping the balance between the required mathematical capability and the child's knowledge is the key to sustaining his/her interest in the learning activity. Therefore, in this environment, learning becomes a progressive dialectic process in which required knowledge (i.e., challenge) and constructed knowledge (i.e., skill) interact and are kept in balance.

The model presented here is hybrid; namely, it consists of two main components: 1) a game module and 2) an embedded instructional module.

The game module is intended to provide a motivating environment for children to engage in mathematical activity, and a context in which children "experience the enjoyment of goal-directed action" [Csikszentmihalyi, 1988, p. 34]. The mathematical activity of the game should ideally deal with a specific and limited domain of knowledge. The game should have a series of well-defined sequential goals. These goals must progressively become more challenging. This challenge should preferably be spread over a number of levels, not only to give children a sense of accomplishment but also to provide them with an indication of how much further they have to go to "beat the game."[1] Naturally, the game should be designed such that to advance through it, children must pay attention to finer and more specific conceptual details and continuously increase and refine their understanding of the embedded mathematical domain to meet the challenges that arise in the course of play. This increase in the degree of challenge is directly proportional to the children's need for increased reflective thought – an essential requirement for deep learning.

The instructional module is intended to allow children to increase their mathematical knowledge. Ideally, this module should not automatically interrupt the flow of play based on pre-determined measures put in by the designer of the environment. Rather, the instructional component should be invoked by children at will, any time they desire. The reason for making the instructional module an on-demand activity is that most children do not like to learn mathematics unless it satisfies a need [for a discussion on children's need for learning mathematics, see Skemp, 1986]. In order to satisfy the need of accomplishing the goals of the game, children have to meet the challenges presented to them. To meet these challenges they have to learn the mathematical concepts that are embedded in the game activity. Therefore, the instructional module must be closely linked to the goals of the game and allow children to construct the knowledge required to move through the game. To keep the ratio between challenge and knowledge construction such that children experience flow, the instructional component must be adjusted to the knowledge requirements of where the player is in the game. Hence, as the game becomes more challenging and knowledge intensive, the instructional module must likewise provide a more sophisticated conceptual presentation of the mathematical domain.

Super Tangrams: An Implementation of the Model

One implementation of the aforementioned model is to be found in a computer-based mathematics learning environment called *Super Tangrams*. *ST* is aimed at helping middle-school children learn two-dimensional transformation geometry. It is designed to take children from no knowledge of transformations to a fairly sophisticated understanding of the subject for this age group.[2] Learning of this mathematical domain is situated in the context of the traditional tangram puzzles game activity. The player is challenged to put together several geometric shapes to fit a given outline. Shapes are moved by applying three transformations to them, namely, translation, rotation, and reflection. In order to play, children have to know transformation geometry, and, as a result, acquire the need to learn the subject. In this section, I focus on the structural characteristics of *ST* that make it a challenge-driven learning environment and an educational flow experience. Other features of *ST* as well as the reasons for its development have been discussed elsewhere [Sedighian & Klawe, 1996b].

There are six factors in *ST* that intensify the challenge and force increased reflective thought in children: 1) the different levels; 2) the user interface; 3) the scoring scheme; 4) the accessibility of the transformations; 5) the order of the puzzles; and 6) the initial configuration of puzzle shapes.

Different levels: *ST* has 40 puzzles divided into 3 levels.[3] *Level 1* starts in an introductory manner so that virtually all children can initially be successful and learn the basic operations of both the game and transformation geometry. *Level 2* becomes more difficult requiring children to pay greater attention to the underlying mathematical concepts. *Level 3* is very complex and requires quite a sophisticated understanding of transformation geometry.

User interface: The user interface in *ST* plays a central role in making it a challenging and reflective learning environment [Sedighian & Klawe, 1996a]. Most children come to *ST* with either no knowledge of or a very limited and naive understanding of transformation geometry. Children are usually accustomed to moving shapes by manipulating them directly. In contrast, in *ST* children have to move the puzzle shapes by adjusting and manipulating on-screen formal interface representations of the transformations (i.e., a translation arrow, an arc of rotation, and a line of reflection). This is initially challenging and requires children to shift from an intuitive to a more formal understanding of transformation geometry. Figure 1 shows how a line of reflection is used to flip a shape -- two handles are used: one to adjust the angle of the line of reflection and the other to adjust the distance of this line from the shape which is being reflected. In each level some of the interface components fade and feedback is reduced thereby putting increased cognitive responsibility on children.

Scoring scheme: Each puzzle can be solved using a minimum number of transformations or moves. Furthermore, each puzzle is assigned a predetermined maximum score which is obtained only when a player solves a puzzle using the minimum required transformations. Extra moves cost the player some points and lower the score. This forces many children to spend considerable time thinking about and determining how to transform the shapes in the fewest number of moves. Puzzles in *Level 3* have very high maximum scores compared with those in *Level 1*.

Accessibility of transformations: Certain transformations or combinations of transformations are easier than others. By restricting the accessibility of certain transformations at different stages of the game, children are forced to understand alternative ways of solving the puzzles. An instance of this is when they are given only reflection to solve a puzzle making the problem much more challenging mathematically than if they are given both reflection and translation.

Order of the puzzles: Puzzles are ordered in such a way as not to distract children from the main objective of the program, which is learning transformation geometry. By this is meant that when the aim of the puzzle is for the child to learn the basics of a transformation concept the tangram puzzle itself is not difficult to solve – sometimes even single-shape puzzles are used. However, as soon as children pass beyond the basics, the tangram puzzles themselves become more complex.

Initial configuration of puzzle shapes: The initial positions of the geometric shapes in each puzzle are carefully chosen so as to create different degrees of challenge. Sometimes a shape is placed so that it can simply be translated to its final position, and sometimes composite reflections are needed to get a shape to its desired destination.

---

[2] An example of what a child is expected to do during play is to determine the angle of rotation and estimate where the center of rotation should be placed in order to move a particular shape to a desired position. This understanding of rotation is not usually expected from students until late in their high school education.

[3] These numbers can be changed depending on how thoroughly the mathematical subject needs to be treated.

To assist children to overcome the challenges faced in the game and stay in flow, *ST* provides them with a *Learn* module. The presentation of concepts in *Learn* is closely tied not only to the mathematical concepts in the game but also to the goals of the game. The *Learn* module can be invoked at any point during a playing session. It has two main features: 1) direct instruction and 2) interactive practice.

Direct instruction: This is an audio-visual teaching component which explains transformation geometry concepts found in children's mathematics textbooks using pictures, text, and voice. Children can activate pop-up windows which are accompanied by voice explanations of the displayed concepts, such as the properties of rotation. Children can invoke these windows any number of times and can exit them at any time.

Interactive practice: This is an interactive multimedia environment in which children can learn and practice the concepts in the game for as long as they want without losing any points. The representation of mathematical objects is identical to those in the game. Children can click on a number of sound icons to listen to explanations of how a transformation works while simultaneously manipulating its on-screen interface representation. The purpose of this feature is not only to assist children to see the consequences of their actions in the light of formal explanations, but also to allow them to gain the required knowledge to meet the challenges in the game. The interface representation of the mathematical concepts as well as the sound icons change for each level to correspond to the needs of the game at that stage. In addition, the sound icons do not simply explain mathematical concepts in a dry manner; in some instances, children are encouraged to learn a concept by statements such as: "This level is for masters of Super Tangrams. Only players who have mastery of transformation geometry can pass this level. So, pay close attention to what I have to say." Figure 2 shows the practice feature of *Learn*.

Figure 1: A puzzle in *Level 1* of the game.

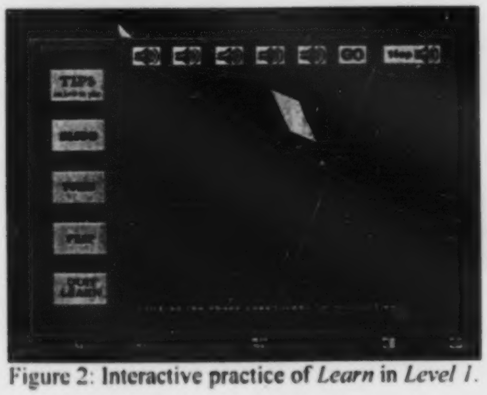

Figure 2: Interactive practice of *Learn* in *Level 1*.

Results

A pilot study was conducted with a version of *ST* which did not have the *Learn* module. Initially, children were quite excited about the program [Sedighian & Klawe, 1996b]. However, as the challenge in the game component started to increase (towards the end of *Level 1*), many children, except for a few who had adult mediation while playing the game, became frustrated and gradually lost interest in the game.

Later on the model of *ST* described in this paper was completed along with several other design variations of *ST*, and a larger study was conducted to evaluate the educational effectiveness of the variations. The study was a quasi-experimental design comprising of a Pretest-Posttest Comparison Group Design and a Posttest-Only Comparison Group Design followed by qualitative interviews. A total of 116 students from five grade-6 classes participated in this study. The students were given pre- and post-tests to measure their knowledge of transformation geometry and their attitude towards the subject. They were also given questionnaires about *ST* which inquired into what they thought they had learned from it, how much they liked it, how they used it, and

BEST COPY AVAILABLE

so on. The students were divided into seven groups, each receiving a different treatment (treatments were based on different variations of *ST*). The students in each group were paired and allowed to work with *ST* for ten sessions of approximately 35 to 40 minutes each. The groups were videotaped during several of the sessions. After the post-tests were administered, 20% of students from each group were interviewed. One of these groups (Group 1; 15 students) used the version of *ST* described above. Another group (Group 2; 14 students) used a version which was different from the former in the following ways: 1) it only had one level, 2) the user interface and the contents of *Learn* stayed the same throughout the game, 3) the scoring was not dependent on the number of moves, and 4) all transformations were accessible at all times.

There was approximately a 50% improvement in the average achievement scores of the students in Group 1. By comparison, there was approximately only a 15% improvement in the average scores of the second group. All students in Group 1 had used *Learn* , and 87% of them had stated that they could not have progressed through the game without using *Learn*. This is in sharp contrast to students in the second group none of whom had used *Learn*, and all had said that they could progress through the game without *Learn*. The log files recorded by the program show that some students in Group 1 had spent more than 25 minutes of a session in the *Learn* module compared with 10 to 15 minutes in the game. Below is a list of some typical comments about *Learn* made by the students from the two groups:[4]

Group 1	Group 2
1. I did [use *Learn*] because you don't lose points learning. [It is good to have *Learn*] because then you might get stuck alot.	1. I did not see it [the *Learn* button]. [It is not good to have *Learn*] because we did not have to use it.
2. I didn't understand what I was doing until I went to *Learn*. I also think that the sound icons were very useful. [It is good to have *Learn*]; other wise you will get stuck and will not know what to do.	2. I did not notice it. I did progress through the game without using *Learn*.
3. I would have never completely understood motion geometry without it [*Learn*].	3. What is *Learn*?
4. [*Learn*] helps people who don't know motion geometry learn it to play the game.	4. We just didn't seem to need it and we didn't pay much attention to it being there.

The students in Group 1 were often observed to be totally engrossed in the activity. When questioned whether they minded that they had to get out of the game activity to learn a concept to be able to continue with the game, many of them stated that it helped them understand the subject better, that they enjoyed the learning because they could apply it directly to what they were doing in the game, and, as a result, could move faster through the game and get a better score.

Conclusions

A model of multimedia mathematics learning environments has been presented in which children become engaged in the learning process through a challenge-driven, goal-directed activity. This model has two main components: a game module and an embedded instructional module. An implementation of this model, *ST*, has also been presented, and the results from the studies conducted using this implementation have been briefly reviewed. The results presented compare the achievements of only two groups. The achievement scores of a third group of 29 students, whose *ST* version was identical to that of Group 1, but additionally received adult intervention, increased on average by more than 52%. These results indicate that an application of this model can help children learn mathematics while really enjoying the learning process.

A number of points have been identified which seem to be crucial for making implementations of this model educationally effective and successful:

1. the game activity must be highly goal-driven and have clear rules of play so that children are at all times *intensely* focused on achieving the goals of the game;

---

[4] All comments are direct quotes from the students.

2. children must continuously receive feedback that is directly linked to the goals of the game;
3. the game must gradually become more challenging and reflective while at the same time providing an instructional component in order to sustain the *flow* experience;
4. to prevent frustration and boredom in children, the dynamics between the game and the instructional component must be fine-tuned; this allows children to receive appropriate instruction for the type and level of the mathematical problems they are solving.

Java for Educational Simulations: Saboteur or Saviour?

Royston Sellman
Department of Psychology
University of Sheffield, Sheffield S10 2TN, UK.
r.f.sellman@sheffield.ac.uk

Abstract: The use of Java as a platform for the construction and delivery of Educational Simulations is considered. Some essential characteristics of simulations are defined with the help of examples. I then explore how effectively Java supports these characteristics by describing the re-implementation of an existing simulation which has been built in several other object-oriented programming environments.

1 Introduction

1.1 Educational Simulations

A educational simulation is a computer based system which brings together a model of some real situation and a graphical representation of the model's output, such as a graph or a moving image.The simulation program allows the user to vary the parameters of the model and then generates its output by running the algorithm across a range of values of a chosen independent variable. For example, Steamer [Hollan et al. 84], a simulation of the powerplant of a large ship, contains a mathematical model of the powerplant's boilers, turbines, heat exchangers and other components. Steamer 's graphical interface shows a schematic display of the system and allows the user to vary parameters and observe the corresponding operating values.

In general, simulation programs conceal their underlying model from the user behind an interface which allows them to vary parameters and observe results. The focus is on the interpretation of these results and their comparison with reality. This leads to different kinds of learning experience from those fostered in modelling systems such as Stella [Richmond et al. 87] or the Dynamic Modelling System [Ogborn & Wong 84]. As one author puts it: "...simulations tend to emphasise the issue of the simulation's fidelity to the real world whereas modelling emphasises the exploration of the consequences of the model." [Brna 91]

Educational simulations have an established role within the area of Computer Assisted Learning where they have been used for many years. The construction of an effective simulation requires three distinct kinds of effort. First, the simulation designers must possess a depth of knowledge on the topic to be treated. They need to be aware of the key concepts, of possible algorithms, the availability of empirical data and so on. Second, consideration must be given to the design of the user's interaction with the software. The most obvious aspect of the interaction is the interface, of course, but as Don Norman [Norman 93],[Norman & Draper 88] among others has pointed out, designers also need to take account of the user's task context, the mode of operation, and a host of other factors external to the actual software. The third and final area of effort is the implementation of the design - the specification, coding, testing and refining of the software package and the production of documentation.

The choice of implementation language inevitably has an effect on each of these stages. Sometimes the effects are obvious - for instance, a particular language might simply be too inefficient to run a complex algorithm. But more subtle effects can also cause trouble. For example, the rise of the Internet is forcing software designers to take account of multi-processing, that is, to be aware that their programs may have to cooperate with other processes running on the same computer. Some languages offer little or no support for this state of affairs. In the following sections I will examine these and other issues.

1.2 Programming Languages

Educational simulations have been built in many different programming languages. I have already pointed out some technical ways in which the implementation language affects a design, but the choice is often mediated by more practical concerns, such as the availability of skilled programmers, or the existence of a compiler for a particular computer platform. Furthermore, to save wasted effort, simulation designers often wish to take advantage of existing libraries of code. The way the programming interface to such libraries is expressed (for example, as a set of C header files) usually constrains the choice of implementation language.

However, I contend that designers of educational software should make their choice of implementation language from a broader perspective, and consider using one of the many object-oriented programming languages. One reason for believing this is that the much touted advantages of the object-oriented approach - code re-use and modularity - are finally bearing fruit with the advent of component architectures such as OLE/ActiveX, OpenDoc, and Java. This is a current industry trend that offers educational software designers a possible solution to a flaw which has dogged their efforts in the past. Jeremy Roschelle notes that "Available software for math and science, while often excellent within its own frame of reference, is failing to meet larger scale needs for re-use of interactive content. Software is too expensive, fragmentary, and incompatible to achieve broad marketplace acceptance. Instead of broadly useful "learning works," we have isolated lesson supports, each with its own idiosyncratic support of capabilities like graphing, communication, assessment, etc." [Roschelle & Kaput 95] This thought is echoed by Neilson and Thomas who stress that "avoidance of the inefficiencies of traditional courseware production is possible only if courseware production is viewed as the creation of reusable resources which address the core subject matter of a domain yet remain sufficiently flexible to permit tailoring to a particular lecturer's teaching style."[Neilson & Thomas 96]

There is no shortage of object-oriented technology on the popular computing platforms. There are several interesting object-oriented languages that have not hit the mainstream, such as Self [Ungar & Smith 96], Eiffel [Meyer 88], Dylan [Apple Computer 92], Beta [Madsen et al 93], and Object Logo [Paradigm Software Inc. 90]. However, the established object-oriented languages, with mature and stable development environments, include C++ [Ellis & Stroustrup 90], SmallTalk [Goldberg & Robson 83], Common Lisp Object System (CLOS) [Keene 89], and now, Java [Jackson & McClellan 96].

1.3 Java

Java is a general purpose programming language with features which make it 'platform independent': that is, programs written in Java run without regard to the kind of computer being used. Java supports object-oriented programming and contains special objects that increase its utility as a platform for distributed computing. Specifically, these objects make it easier to build programs which pass data between different computers on a local or wide area network. Java is a compiled language rather than one which is interpreted line-by-line. More accurately, Java is compiled into machine independent 'byte codes' which are then interpreted at run time by a software 'virtual machine'. The virtual machine must be implemented for each platform Java is to run on.

Java's variety of object-orientedness is based on classes rather than prototypes. This means that the programmer must first define all the methods and variables of a class and then proceed to create instances of the class to form the objects which do the work of a program. This class-based approach can be contrasted with that of prototype-based languages, such as Self, in which objects can be defined and instantiated in one pass. It has been argued [Drescher 87] that the prototype-based approach is equivalent in expressive power, and much easier for programmers to learn, than the class-based paradigm. It has also been pointed out that class-based languages lead to inflexible code which is less readily adapted to a new purpose or context [Stein et al xx]. On the other hand, proponents of class-based languages claim that the methodology encourages preferred software engineering practices such as top-down planning.

There is less equivocation with regard to Java's support for inheritance, the mechanism by which a class descended from a parent superclass inherits methods and variables. Specifically, Java only weakly supports multiple inheritance; classes can inherit directly from only one parent, plus they may (in Java terms) implement an interface to one other class and gain access to methods and variables defined therein. This might seem to be an esoteric point, but multiple inheritance is used to strong effect in several class libraries (such as MetroWerks'

PowerPlant [MetroWerks 96]) where it allows for more compact and flexible code. Java's low level of support for multiple inheritance has attracted some criticism.

Java supports multi-processing through threads, which are objects to which the system apportions regular slices of processor time. When given the central processor's attention a thread executes its run method, into which the programmer can place relevant instructions. Threads are useful, especially so given the asynchronous nature of today's event-driven and Internet connected systems, and they are relatively easy to program. A common situation where threads find a use is in the downloading of text and graphics to a Web browser. The text and graphics of a Web page are stored in separate files on the server and quite often the graphics files are much larger then the text. The channels through which the two datatypes move to the user's browser are typically powered by separate threads, each moving at their own pace. A third thread is polling for user input and driving the browser's interface, which means the user can scroll the Web page, and click on URLs, without having to wait for the graphics to finish downloading.

The built in functionality of Java can easily be extended with libraries written in Java itself, or (with a little more difficulty), any other language. Libraries can be loaded dynamically, at run-time, even over a network. However, at present there is no provision for unloading a library, which makes it possible to carry on filling up memory, but this is expected to change in future.

One of the libraries that Java comes with as standard is the Abstract Window Toolkit, or AWT. This allows programmers to construct graphical user interfaces which will have a similar appearance across all the platforms that support Java. The AWT though, is lacking in many of the interface elements and widgets that designers for the MacOS, or Windows, or Motif, are accustomed to using in their software.

Java's support for media is a mixed bag: Java knows about text and a few fonts and styles, but not to the level programmers of other platforms are used to. Java currently can handle just one kind of audio file, a low quality format proprietary to Sun Microsystems Inc. Java can access static image data stored in GIF and JPEG formats but has no support at present for moving images such as Quicktime or MPEG movies. However, media support is certainly an area where Java will be improved in future releases.

Finally, Java does not possess any introspective features. That is, Java programs can't easily treat other Java programs as data, and can't create, manipulate and execute pieces of Java code on the fly. Programmers used only to C, C++ or other static languages will not miss this capability. But Lisp programmers, who are used to creating parsers and lightweight language interpreters in just a few lines of code, will bemoan Java's shortcomings. In mitigation, Java's defenders can point to the compactness of Java code.

With this rather large list of concerns in mind I now move on to describe an existing educational simulation which I have partially re-implemented in Java.

2 Gravitas

2.1 Gravitas in Object Logo

Gravitas [Sellman 92] is a dynamic simulation which offers the user the experience of working with mutually gravitating objects in a 2-d space. Users can easily build their own Solar System, or asteroid belt, or shuttle launch, and observe the time evolution of the system. Gravitas calculates all the forces between the gravitating objects and animates them smoothly across the screen. Users can alter initial conditions, and they may vary parameters during the simulation using a Direct Manipulation [Shneiderman 83] style interface.

Furthermore, Gravitas is fully user-scriptable via a simple programming language. This scriptability leads to some novel patterns of use, such as multi-stage rocket journeys between orbiting bodies [Sellman, 94, ch. 3] and the observation of solar systems with evaporating central stars. Even very simple scripts (less than 10 lines of Logo) can usefully expand Gravitas' capabilities, for example by providing a function which measures the kinetic and potential energy of a system. Figure 1 shows a version of Gravitas written in Object Logo [Paradigm Software Inc. 90], a powerful dialect of Logo for Macintosh computers. The figure shows four imaginary celestial bodies heading for a collision. The trails of the moving bodies are just visible, and the control panel at left displays the relevant physical parameters.

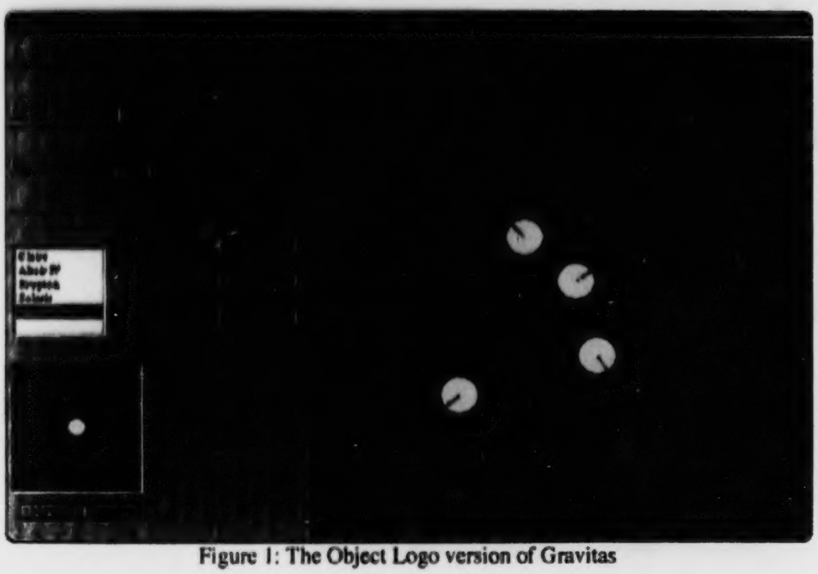

Figure 1: The Object Logo version of Gravitas

Studies with real users indicate that Gravitas offers new ways of learning physical concepts such as gravitational force, momentum, conservation laws and orbital mechanics. Writing this version of Gravitas in Object Logo demonstrated the efficacy of the dynamic, object-oriented approach to constructing such systems: the Object Logo version was built in a much shorter time than a subsequent implementation in C. The simulated celestial bodies, and the other components of Gravitas, such as viewers, gauges and buttons, are implemented as first class objects, in the sense that they have their own private data and methods for generating behavior and appearance. Many of the Logo objects underlying the interface components have been re-used in other programs.

2.2 Gravitas in Java

Figure 2 shows the re-implementation of Gravitas in Java.See also http://www.shef.ac.uk/~pc1rfs/gravitas.html

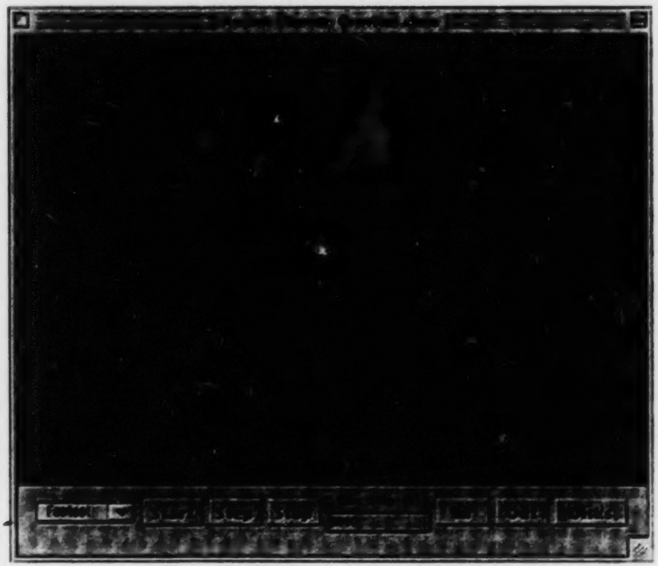

Figure 2. The Java version of Gravitas

BEST COPY AVAILABLE

The Java version (implemented here as a Java applet) is missing many of the features of the original Gravitas; most significantly it is not scriptable by the user. Of course, this can be fixed in future, given time, but our main purpose here is to highlight those Java features of general interest to educational simulation designers that the new implementation exposed. Some of these features are visible on the screen, others are no less important but are hidden in the Java code. I describe a selection below.

Interface items:

The figure shows a system containing four celestial bodies representing the planet Jupiter and three of its moons. These bodies are displayed in a viewer representing a region of space. The viewer can be panned and zoomed to view objects which have travelled out of range. The objects can be dragged into position in the viewer with the mouse to allow the investigation of arbitrary configurations. Dragging with the mouse requires some way of recognising that the mouse is over an object and although Java only offers built in support for hit-testing of rectangular graphical objects, it was not difficult to implement a custom algorithm which detects mouse events inside the diameter of a planet or on its label.

For the dragging just described and for driving the simulation I implemented a smooth, flicker-free animation engine. Java supports this by allowing the programmer to compose complex graphical images in off-screen buffers called images. The contents of an image can then be drawn to the screen without flicker by using an efficient rectangular area copy method. Java's image objects are used in a second context also: the celestial objects have a 3-d appearance, as if they were illuminated from above and left (something of a paradox as the objects only move in two dimensions; however, this allows for future expansion). The shaded appearance is computed by a standard algorithm just after the object's viewer size is calculated, and then stored into an offscreen image which is drawn into the viewer, when required, by the same efficient copy method.

Several common interface widgets are visible in the figure: menus, labels, buttons and gauges. Each of these objects is a descendant of the Java Abstract Window Toolkit component class. This means they each receive events from the system and have their own methods for handling them and can therefore work in new contexts. Java has a built in button object which covers most uses, but Gravitas required some special behaviour - a button which acts for as long as it is pressed, for instance - so I developed a custom button class which has its own methods to generate appearance and behaviour. Getting custom components such as these to communicate with the rest of the program is particularly straightforward in Java. The custom buttons simply send event objects to the applet's event handler method which can then take the appropriate action. No other internal 'wiring' is necessary. Several C++ application frameworks could learn a lesson here (eg. [Metrowerks 96]).

Underlying objects:

The celestial bodies are a implemented as an independent Java class with its own private variables and methods. The variables, representing mass, position, velocity and so on, are manipulated through the use of setter and accessor methods. This is standard object-oriented programming practice, and it ensures that changes to an underlying representation do not have repercussions throughout the program as a whole. Java encourages this kind of structure but does not actively support it by, say, automatically creating setter and accessor methods for each class variable. Instances of the celestial object class store the positions and velocities in high precision floating point variables (Java doubles) to reduce errors. They also store the precomputed shaded images mentioned above.

The Java implemented celestial objects do not have a method for drawing themselves. Instead, viewers do all the drawing and maintain a list of depictable objects together with a method for drawing each type of depictable object. This separation of object and depiction will in future allow the addition of different kinds of depiction method, such as one which looks like a spacecraft, or one which looks like the real Jupiter. Of course, programmers are able to separate functions in this way in conventional languages too, but it requires some ingenuity in say, C, whereas in Java it seems natural.

The mathematical engine, which computes the forces between each pair of bodies in the viewer, is implemented in a separate Java thread object. This thread is serviced regularly by Java (every millisecond or thereabouts) and so it had to be implemented in a very fine grain way to avoid locking out the thread servicing the interface. If there are n objects in the viewer, then to take account of every gravitational interaction in the system, n2 calculations have to be made during each step. If these were all done in one go then the interface thread would receive little of the processor's attention and the user would be faced with a very sluggish applet interface. So it is arranged for just one interaction to be computed at a time, and the screen is only updated when a whole set of calculations is finished. In a more advanced multi-tasking system this responsibility would be taken out of the programmer's hands and left to the operating system (as it is in Unix for example), but Java, being platform independent, can not make the assumption that this feature is present.

2.3 Comparison of Java and other implementations

Compared to other implementations of Gravitas the Java version's major deficiency is lack of end user scriptability. It would certainly be possible to build an interpreter in Java for a suitable scripting language, but it would require a much greater effort than the same task in Lisp or Logo, where the introspective features mentioned above (in section 1.3) give the programmer access to the underlying interpreter. In this area, Java is a loser.

Another weak area of Java is performance. On a PowerPC, the mathematical engine runs about one tenth as fast as an almost identical engine written in C++, and it is less than half as fast as the Object Logo engine, which is also working to slightly higher precision (although this is of little importance). However, not too much should be made of these figures as they are very rough, they do not take account of improvements which can be obtained with the use of so-called Just In Time Compilers, and the underlying Java system has still some way to go before it is fully optimised for the PowerPC. Furthermore, programmers can escape from Java performance bottlenecks by writing 'native methods' - code written for a specific platform and imported dynamically by Java at run-time. The cost of this technique is of course a loss of portability.

At several points in the development of Java Gravitas the Abstract Window Toolkit's lack of support for irregular shaped screen regions was found to be a nuisance. MacOS and Windows programmers are used to these constructs, which make it easier to do proper hit-testing and flicker free screen updates. Although a workaround was developed here, it is far less efficient than the real thing. Fixing this shortcoming will require an overhaul of Java's Abstract Window Toolkit.

Java's much vaunted removal of the burden of memory managment from the programmer proved to be partly a mirage. It is true that the really low-level tasks (allocation and deallocation of blocks of memory for data structures) are gone, but it is still possible for the careless programmer to create invalid (or null) pointers, which halt the Java interpreter (much less serious than crashing the computer) and have to be debugged. Also, wise programmers keep track of how many objects they are creating as this process carries some overhead and can lead to sluggish performance.

3 Conspicuous Advantages of Java

Without doubt, it is exciting (to a programmer at least) to build a Java applet like Gravitas, install it on a Web server, and then tour around an assortment of Internet connected computers (perhaps, if budget allows, in foreign countries) and see it running. However, there are less frivolous advantages. If we ignore the question of charging for the use of applets (a topic beyond the scope of this paper), then the problem of distribution, which is especially acute for educational software, since there is little commercial support, is drastically reduced.

Summarizing the barriers to the portability of electronic learning resources (in the pre-Java era) Collis & De Diana set out four categories of obstacle: a) technical factors; b) educational factors; c) social/cultural factors, and d) organisational factors [Collis & De Diana 94]. While not a panacea, it is clear that Java can have a strong impact on categories a) and d).

Turning the process around, Java also gives applets a window on the wider world of the Internet, making it more straightforward to 'plunder' online resources. Although Gravitas does not support it currently, I have begun work on a Java program to extract data from online astronomical tables such as http://www.navcen.uscg.mil/gps and use it to automatically generate orbital systems in Gravitas.

BEST COPY AVAILABLE

Going a step further, if enough people build good quality educational applets, which can be tailored to individual teaching styles (here the scriptability discussed above can play an important role [Sellman 94, ch. 4]) then perhaps the Internet can be the vehicle for an 'educational SuperInterface' [De Diana & White 94], to 'support large scale telestudy' and augment current distance education practices.

4 Summary

So how does Java come through this examination? The major drawback from the point of view of Gravitas is the amount of extra work that would be needed to achieve scriptability. And, as I have contended above, far from being an esoteric requirement, scriptability is one key to providing flexible educational simulations. Still, this issue is not a showstopper, merely a hurdle.

Java's outright performance is still inadequate for many situations. It is not unusual for educational models to use algorithms whose time performance for a number of objects n is O(n2) or worse, and Java has a high price in such situations. New Java technology will close the gap with traditional languages such as C++, but when or even whether it will truly catch up remains to be seen.

Java has a reduced set of user interface components or 'widgets' compared to those a designer working with the MacOS, or a Windows variant, or a Unix graphical interface toolkit, is used to. But educational software seems to have coped with relatively unsophisticated (but not badly designed) interfaces, so perhaps this is not such a serious drawback.

Gravitas does not make much use of multimedia datatypes and so Java's weakness in this area was not a hindrance to development. However, it could be a serious obstacle for an application that relies heavily on sound or video. Undoubtedly, there are strong commercial pressures for Java to improve its support in this area, and assuming this leads to an extended Java standard, rather than piecemeal solutions, then educational software will be able to reap the benefit.

File handling is another area Java Gravitas does not exploit. In fact file handling is problematic for Java applets, because security restrictions mean applets cannot open files on the local system of the browser they are running on. They can, however, create and manipulate files on their server, which is adequate for some uses.

Above all, Java is a fast moving technology with a lot of development momentum behind it. A new version, Java 1.1 is expected in early 1997. There is a good chance that the obvious flaws will be hammered out. For educational simulations at least, Java represents a great opportunity. A Saviour perhaps, and certainly no Saboteur.

Designing a Web Browser for Children

Robert Sheehan
Department of Computer Science
School of Mathematical and Information Sciences
University of Auckland
New Zealand
r_sheehan@cs.auckland.ac.nz

Abstract: The World Wide Web is a wonderful resource for children. It can be used to educate, excite and entertain. Until very recently there have been no Web browsers designed explicitly for children. In this paper we look at some preliminary design decisions for a children's browser, including a simple text to speech tool, graphical previews of pages before the link is selected, graphical history lists, and themes. We provide ways to interact with web pages as well as look at them and select links.

Introduction

Children have been using the World Wide Web for several years now. There are thousands of sites which are designed specifically for children to access. A few of the better known ones are *Yahooligans*, *Kids connection*, *Kidscom* and *Kids space*[1]. Some of these, the best known probably being *Yahooligans*, include databases for children to search to find items of interest. These databases have been constructed to contain references to information useful or appropriate for children, rather than being general purpose Web databases.

A vast amount of work is put into these child centred sites. The interesting thing is that until very recently [ConnectSoft] no one has designed a Web browser specifically for children, or allowed the major browsers to be customised enough to give them more *pleasure-of-use* [Oostholt et al. 96] for children. This paper presents the design of a browser for children which helps the user move around the Web without relying on text. The interface to the browser is designed with children's interests in mind. It also encourages children to customise the browser and modify and interact with the material it presents from the Web.

We look at some of the things which are wrong with current browsers if they are to be used by young children and describe some of the solutions we are trying in our browser, known as *Scooter*.

Current Browsers and Text

There are several ways in which current browsers can be improved to make them better for children. The first is by cutting down the reliance on text. Much of the content of the Web, not in the number of bytes transmitted but in the amount of screen real estate which is used to display it, is text - even on sites designed for children. This is understandable given that HTML (HyperText Markup Language) originally concentrated on ways of presenting text. Text is compact, easy to transmit and generally carries the sort of information educated adults are most familiar with.

Many of the children's sites are designed for children in the age range from eight to twelve, which covers a very broad range of reading ability. Many authors of these sites assume that only children able to read and comprehend text will use them. Sites which are designed for younger children frequently employ less text, and the text which is provided may be intended for adults or older children to read to, or along with, the younger child.

The links on these sites are sometimes text only; others include graphic buttons as links. Unfortunately it is frequently difficult to make out what connection the graphic has to the linked page. The text usually contains more information.

---

[1] See [Resources] for URLs.

Text also monopolises in other areas where a more graphical approach would be useful, this time in the browsers themselves. The history lists which browsers maintain are either the titles of the recent pages or in the worst case the URLs (Uniform Resource Locators) of recent pages. Similarly the bookmarks which users maintain to keep track of pages they want to return to are always textual. The browsers' menus and dialogue boxes suffer from the same limitation.

These resources are thus impossible for non-readers to use, and difficult for beginning readers[1].

The Children's Browser and Text

As we have seen, not only is much of the content of many Web sites provided as text, the history and bookmark lists are also stored as text. Many of the links are only provided as text.

In order to open-up use of our browser to beginning or non readers one of our key decisions is that it should be possible to translate all text on the screen into speech by the browser. We are investigating the use of technology such as that provided by Apple's *Plain Talk* [Apple Computer, Inc 95]. *Scooter* has a speech balloon or talk tool [Fig. 1] which can be clicked to read all the visible text on the current page. If a child wants to read a specific block of text, that text can be dragged to the talk tool button. The print tool button functions analogously: clicking the print tool button prints the whole page; dragging a picture or a section of text to the print tool causes the picture or text to be printed.

The title of the page is spoken as soon as the page is displayed. Highlighting of the text as it is read is used to help the children make the connection between text and words. *Scooter* does not have text associated with its tool buttons. If the child holds the mouse pointer over a tool button for more than a second it causes a brief description or name to be spoken, e.g. "I am the talk tool, drag words to me and I will read them to you".

Whenever a question needs answering via a dialogue box *Scooter* automatically reads the question and the possible replies are read in turn and when the pointer hovers over them.

Links

We also have a secondary attack on the problem of text. After displaying a page *Scooter* also downloads each page pointed to via a link from that page. The pages aren't shown automatically, but are stored to display a preview to the user. This is similar to the method used in the WebBook [Card et al. 96] system, except in that case a book of related pages is constructed. When the user moves the pointer over a link and holds it there for a second a preview of what that page looks like is displayed. This preview is displayed directly over the link's position on the display. A click on the preview activates the link.

One difficulty with this is the time required to download all the pages and generate the previews. Not only does the page have to be accessed but any graphics (ignoring animations for the time being) have to be downloaded. The graphics are essential because the preview is supposed to give the user a good idea of what the page looks like if it is selected.

To solve the problem of slow connections we suggest adding a page preview capacity to pages which are likely to be accessed by children. A page preview graphic is pointed at via a <META> tag, including the string "preview" in the name field and the URL corresponding to the preview in the content field. As in

<META name = "preview" content = "http://www....">.

Our recommendation is that the preview graphic shows what the top of the page would look like in a browser window filling a screen of 640x400 pixels. The preview itself should be reduced to a graphic of 160x100 pixels, to speed transport and allow suitable display. Partly because of these specifications *Scooter* needs a screen of at least 800x600 pixels.

---

[1] We have observed that the frustration of not being able to read text on a computer screen has helped provide the motivation for some children to work harder on their reading.

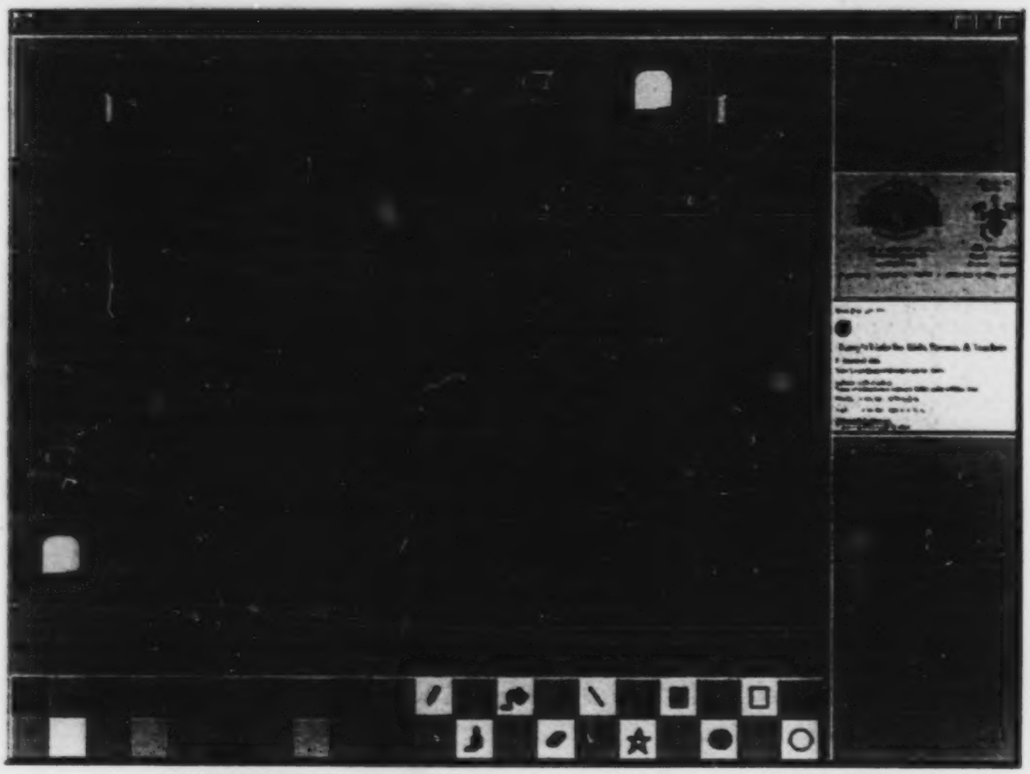

Figure 1: Screen shot of Scooter, showing the drawing tools and history list.

After downloading a page, the browser starts contacting each potential link site and determining whether or not a preview graphic is held. If it is the preview is downloaded, ready to be displayed when the user moves over the link, otherwise the whole page is preloaded and the preview is generated by the browser. This can be turned off if necessary, restricting previews to those pages which are cached.

Authors including page previews of their pages should adhere to some simple recommendations:

- If the page includes frames, the frames should be ignored in the preview to cut down the clutter and leave more space for the focus of the page.
- The main section of the page should be the previewed area.
- One or two medium sized graphics are more useful than lots of little ones.

An aside: We suggest that the best pages from a child's point of view are those that retain their visual interest even when reduced to 1/16th of the intended size.

An added side effect of fetching these previews is that the browser can determine links which are no longer valid or have been moved before the user selects the link.

It should be clear that we are not intending such a strategy to be used on pages which do have a very large number of links. In Web pages designed for children we see no justification for long pages with lots of links. Even sites which provide large useful indexes should be broken down into related areas. So to all authors of pages for children we add further recommendations:

- Keep the number of links on a page down to a small number (less then ten, excluding forwards, backwards, and escape links).
- Design the page so that it can show the most important information in a window of 640x400 pixels.
- The whole page should take up no more than three 640x400 displays.

BEST COPY AVAILABLE

History Lists

Scooter also stores these previews in the history list [see Fig. 1]. Of course the previews may be out of date, since the page they refer to has changed. The preview graphics are updated whenever the page is visited. The history list is shown in a separate section of the window. At the moment the history list uses full 16th size previews. We may shrink them down further to accommodate more pages. Holding the mouse pointer over a history list item causes the title of the page to be spoken.

Bookmarks and Treasure Chests

Lists of favourite sites, or bookmarks, are also augmented with previews of the contents of the sites. In the same way that current browsers allow users to type in any name they want to remember the page by, *Scooter* allows spoken or pictorial names. Pictures produced by users can replace the previews if desired. If a spoken name has been given, holding the pointer over the textual or pictorial name causes the child's recorded name to be replayed. Otherwise the standard textual name is spoken.

The bookmarks themselves are actually stored in a treasure chest. This is a multipurpose container for any objects the user wishes to keep.

Since a page preview of the current page is automatically placed in the pictorial history list when the page is displayed it is easy for a user to add the current page to the treasure chest by dragging the preview from the history list into the treasure chest. A dialogue box asks if the user wants to give the page a name.

Toolbar Buttons and Customisation

Apart from adding the talk tool we have reduced the number of buttons which appear in the toolbar, compared to currently popular browsers. This is both to simplify the use of the browser and allow more screen space to each button. Small buttons are difficult for small children to hit correctly. Currently our toolbar has forward and backwards buttons, home, treasure chest, find, print, and speak.

Something children really like doing is customising their belongings. One of the features of *Scooter* is the ability to select a theme for the buttons and the general appearance of the browser. For example the *Creepy* theme has a haunted house for home and skeleton hands for forwards and backwards.

Doing More with the Content

Current browsers do provide the ability to work with the content downloaded from the Web, but in very limited ways. The page itself can be saved (usually this loses any graphics associated with the page because the links are relative and the graphics are cached with their original addresses). Text or graphics can be copied from the browser window and then pasted into another application for manipulation. Sometimes graphics and links can be dragged onto the desktop, where they take on a completely different appearance, usually the icon associated with URLs.

If users want to do something with the text, graphics, sound or video clips, they must open up other applications, separate from the browser to work with them. This adds an extra level of complexity in dealing with the Web material. It is very common for children when they first start to use computers to say "Why can't I do that here? I could yesterday". The problem is that the child, understandably, cannot see why there is a distinction between different programs, and just because the same object appears in two programs, doesn't mean that the tools from both programs can be applied to it[1]. A particularly good child related example is to do with colouring pictures. Several children's Web sites provide black outline gif images which users are supposed to print out and colour in. Why not provide a colouring set (and other painting tools) within the browser itself?

This is what we have done with *Scooter*. And until we completely break down the user interface barriers which exist between programs we need to add further abilities to our browser to do *natural* things with the content.

We still have to determine the list of things which a child could reasonably expect to be possible. Currently simple drawing tools are provided to allow the user to make additions to graphics or design their own buttons, or draw representations of pages for the bookmark list.

---

[1] This raises lots of further questions which are much broader than making a better browser

We are left with the question of what to do with pages once they have been altered. At the moment the changes are only maintained during the current session. We are investigating saving the changes as annotations to cached copies of the original page. This approach means that the changes will only be visible to other people using *Scooter*. There are several other approaches we are also investigating, which will allow such altered pages to be visible on other browsers.

The treasure chest, mentioned above, is designed to accept all Web page elements: text, graphics, video, and audio. Dragging and dropping graphical, and other, elements to the treasure chest is intuitive and very visual. The page element itself, rather than an unrelated icon, moves into the treasure chest, leaving a copy behind. At the moment the treasure chest is an unorganised conglomeration (a bit like a child's room). We need to investigate automatic ways of sorting the material, always giving the user the final choice.

Where to Now

The first version of *Scooter* is written in Java and apart from the talking aspect is designed to be platform independent. At the moment the talking *Scooter* is restricted to the Macintosh until we find a platform independent text to speech translator.

We still need to test most of the recommendations to see how much they contribute to making the browser more useful and pleasurable for children. And we still have several unsolved user interface problems, some of which are mentioned above.

Multimedia Courseware for Teachers: Providing Flexible Professional Development

Cathie Sherwood
Faculty of Education
Griffith University
Nathan 4111
Australia
C.Sherwood@edn.gu.edu.au

Abstract
This paper discusses the rationale behind the development of an interactive multimedia CD-ROM which focuses on the use of new media in classrooms. The Multimedia and Information Technology Across the Curriculum (MITAC) CD-ROM is designed to provide opportunities for teachers to develop their own models of best practice using interactive technology across the curriculum. Through peer mentoring, ongoing support and a flexible schedule which provides adequate time to practice and implement new learning strategies, teachers are able to meet their professional development needs in a new and rapidly changing area.

Introduction

The influx of computer technology, and instruction with and about computers, has been a key theme in education over the last decade. Over this period, the number of computers in Australian schools has increased dramatically, as has the level of knowledge and expertise required of teachers to effectively integrate computer technology into the curriculum.

It has been acknowledged that in strongly urging (often requiring) teachers to use information technology (IT), especially computers, as an integral part of their teaching, they are being asked to undertake a considerable amount of personal learning. Such learning is not only with respect to working with a new technology, but in full consideration of its impact on the curriculum and change in curriculum practice. If the potential of computer technology is to be exploited fully, new teaching styles have to be developed to support new modes of learning. Consequently, the traditional role of the teacher requires critical review, particularly when teachers themselves select the technology options most appropriate to content-learning tasks. In whatever way schools may change in the future, it is how teachers view technology and their preparation to use IT to instruct, manage and evaluate which is critical to the effective integration of IT into the curriculum.

Professional Development

There are very few opportunities for teachers to engage in learning activities to assist them in becoming competent and confident users of the new technologies. Teachers are not always able to attend inservice activities or university courses, which may be timetabled at inconvenient times, nor do they necessarily have the confidence or knowledge to explore technological options in their own time, even if they do have the requisite hardware and software. Where IT has been used in school programs it has usually been introduced by enthusiastic individuals with particular expertise and interest in the area.

In addition, research has shown that traditional face-to-face inservice approaches do not always result in a long-term change in practice [Wilson 1990] [Zammit 1992] [Sherwood and Buchanan 1993]. Many educators who complete an IT-related professional development activity are initially enthused and committed to the implementation of the technology into their classroom. However, this initial enthusiasm wanes quickly (unless appropriate on-going support is provided) as the reality is that few teachers get the time to experiment, learn and practice integrating new technologies into their classrooms.

Teachers are the ultimate gatekeepers in classrooms. Therefore, it is critical that teachers *are* provided with the skills and confidence to explore technological options for their classrooms and schools with the clear intention of enhancing student learning both about and through information technology. Enabling teachers to become proficient, critical users of IT, involving them in IT planning and diminishing their physical remoteness and/or sense of isolation, requires a high level of commitment and involvement from all education stakeholders including education authorities and universities.

Developing a Multimedia Professional Development Resource for Teachers

In Queensland, in the last five years particularly, there have been a number of collaborative activities between teacher education stakeholders designed to meet the professional development needs of teachers in IT. During this period, the move by Australian universities into more flexible approaches to delivering education has coincided with an initiative of the Commonwealth Department of Employment, Education, Training and Youth Affairs (DEETYA).

From 1994-1996, DEETYA provided funding under a National Professional Development Program (NPDP) to provide resources to assist teachers in the renewal and extension of their teaching and to help them to improve work organisation and teaching practices within their schools. An important focus of the NPDP was "to provide teachers with the opportunity to play a central role in determining their own professional development needs within the context of emerging national priorities and the goals for Australian schools" [Department of Employment, Education, Training and Youth Affairs 1996]. Professional development activities were designed to assist in the renewal of teachers' discipline knowledge and teaching skills and in helping teachers to improve work organisation, practices and teaching competencies within schools. A second key feature of the NPDP was that it encouraged and supported partnerships between universities, education authorities, teacher organisations and schools.

The increase in the number of interactive multimedia (IMM) applications available for use by schools and the interest shown by many teachers in multimedia as a development tool for themselves and their students led staff at two of Queensland's universities (Griffith University and The University of Queensland) to apply for, and receive, NPDP funding in 1995 to redesign a Graduate Certificate in Computer Education (Multimedia).

While the two universities offered a number of subjects with a focus on the integration of IT into classrooms, neither offered a suite of subjects that:

- could meet the professional development needs of teachers in a new and rapidly changing area
- provided an inservice model which had relevance to the teachers' own curriculum
- enabled teachers to be mentored by their peers
- provided adequate time for teachers to practice and implement new learning strategies, and
- provided ongoing support as well as recognition for teachers' efforts.

An advisory group to assist the project directors was established at the outset of the project. Members of this Project Reference Group were representatives of national and state teacher professional associations in all eight Key Learning Areas together with representatives of primary and special groups.

The outcome of the NPDP grant is the Multimedia and Information Technology Across the Curriculum (MITAC) CD-ROM which has been jointly developed by the two universities in cooperation with the Queensland Department of Education, and enables teachers to gain an understanding of information technology (with a focus on multimedia) and how it can be integrated into classrooms.

The broad client base targeted by the MITAC CD-ROM is that of educators in general. Traditional courses in this area depend on student attendance on-site or a long term commitment to enrolment in a course of study. These options are not suitable for many educators who have work, study or family commitments. The CD-ROM medium in itself ensures a degree of portability and flexibility for teachers, as does its cross-platform application (Macintosh and Windows). MITAC can be used either on an individual's personal computer or in a classroom/laboratory setting, depending on the preferred method of learning. Additionally, the fact that individual modules of MITAC can be undertaken on an as needed basis, means that learning can be targeted and immediate.

The MITAC CD-ROM

The MITAC CD-ROM provides current, flexible and practical multimedia training for educators. It contains all content required for the Graduate Certificate of Computer Education (Multimedia) including text, software demonstrations, interviews, sound files, and videos as well as a number of case studies which demonstrate best practice. These include a range of practical examples showing how teachers incorporate interactive multimedia as part of the teaching/learning process.

Advantages

One of the most obvious advantages of the MITAC CD-ROM is that it allows the process of exploration to be controlled by the learner, and therefore facilitates exploration without imposing assumptions about the user's prior understandings or commitments. Teachers can work through the material in their own time and at their own pace. It also provides:

- activities which are based primarily on the needs and concerns which teachers themselves identify
- the opportunity for teachers to take responsibility for their own learning and construct their own knowledge
- for the expertise of the teacher to be acknowledged
- opportunities for collaborative and collegial activities so that professionals are joined in working partnerships
- engagement of teachers in critical reflection of their teaching practices
- opportunities to integrate theory and practice.

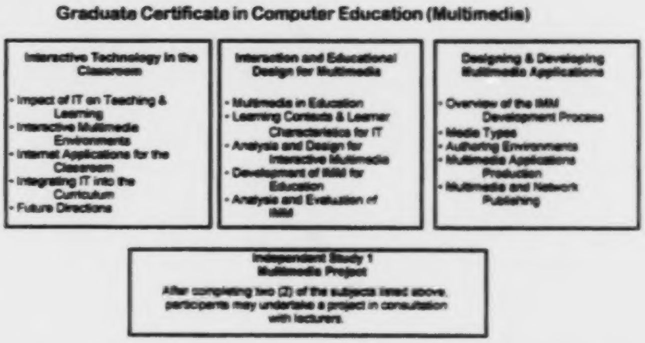
Structure

The four subjects in the Graduate Certificate of Computer Education (Multimedia) are:

- Interactive Technology in the Classroom
- Interaction and Educational Design for Multimedia
- Designing and Developing Multimedia Applications
- Independent Study (Multimedia Project)

These four subjects together address the complexity of classroom activities from the role and impact of IT on pedagogy, multimedia tools for learning, to management of resources and school organisation. Teachers can use MITAC either individually or in groups, in a classroom setting or at home, as a complete qualification or a modular approach to professional continuing education.

The structure of the Graduate Certificate (including modules) is as follows:



Graduate Certificate in Computer Education (Multimedia)
Interactive Technology in the Classroom
- Impact of IT on Teaching & Learning
- Interactive Multimedia Environments
- Internet Applications for the Classroom
- Integrating IT into the Curriculum
- Future Directions
Interaction and Educational Design for Multimedia
- Multimedia in Education
- Learning Contexts & Learner Characteristics for IT
- Analysis and Design for Interactive Multimedia
- Development of IMM for Education
- Analysis and Evaluation of IMM
Designing & Developing Multimedia Applications
- Overview of the IMM Development Process
- Media Types
- Authoring Environments
- Multimedia Applications Production
- Multimedia and Network Publishing
Independent Study 1
Multimedia Project
After completing two (2) of the subjects listed above, participants may undertake a project in consultation with lecturers.

Figure 1: Overview of the Graduate Certificate of Computer Education (Multimedia)

Each module is interactive and can be accessed in any order. For each subject, appropriate assessment items are outlined. Suggestions for self-assessment are provided for each module along with reflection activities. The fourth subject is a project involving the development of interactive multimedia courseware to support an instructional need in the teacher's own situation.

BEST COPY AVAILABLE

By providing opportunities for teachers to select and develop their own content and learning processes, they are given opportunities to develop new kinds of pedagogies for use across the curriculum and to develop models of best practice using information technology.

Navigation and Content

One of the most important considerations in designing MITAC was to ensure that teachers with varying levels of IT expertise were able to use it competently. The framework is intended to give continuity of design and use throughout all the subjects that are contained on the CD-ROM. Once one subject has been completed, teachers are familiar with the layout and tools for all other subjects.

Entry to the material contained on the CD-ROM is via a 'campus map' which contains building icons for each of the four subjects along with an information booth. The map can be accessed from any screen.

Figure 2: Campus Map (Main Menu)

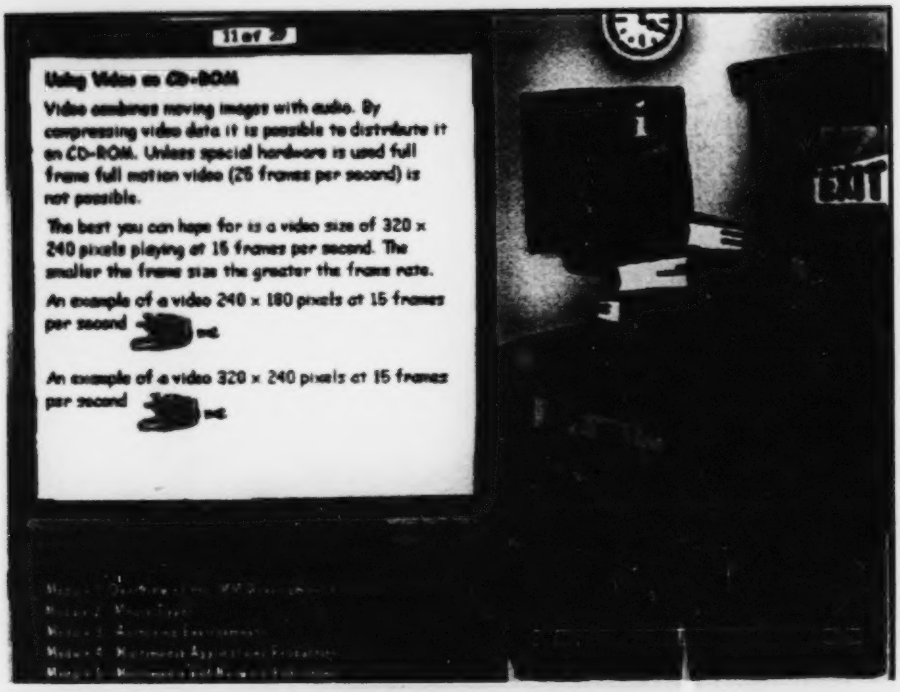
The **Information Booth** provides information about each of the subjects and other aspects of the CD-ROM.

The **Glossary** provides further explanation for terms used in the program.

The **Resource Centre** contains the readings which can be printed out, movies and animations, software demonstrations and audio files.

The **Assessment** building contains the assessment items required for each subject. It also contains the activities which must be undertaken by teachers if they wish to receive acknowledgment for professional development purposes.

BEST COPY AVAILABLE



Using Video on CD-ROM

Video combines moving images with audio. By compressing video data it is possible to distribute it on CD-ROM. Unless special hardware is used full frame full motion video (25 frames per second) is not possible.

The best you can hope for is a video size of 320 × 240 pixels playing at 15 frames per second. The smaller the frame size the greater the frame rate.

An example of a video 240 × 180 pixels at 15 frames per second

An example of a video 320 × 240 pixels at 15 frames per second

Figure 3: Example of a screen in one subject

In each module there are buttons labelled *Show Me*, *Tell Me*, *Reading* and *Reflection*. *Show Me* usually brings up a QuickTime movie which can be, for example, a demonstration of a software package, an interview excerpt or an animated sequence. *Tell Me* provides additional information about terms, concepts and ideas used in the application. The *Reading* icon brings up articles from current journals or the World Wide Web. Selecting the *Reflection* icon will bring up screens with questions which prompt the user to consider issues as they apply to their own teaching situation.

Teachers have access to current sources of information about available software and can enhance their critical analysis skills to make judgments about its appropriate use in specific learning environments.

Trialing of Modules

One of the most important aspects of this project has been the involvement of teachers at all stages of design and development. Each member of the Project Reference Group nominated teachers considered to be either experienced in the use of IT in their classrooms or interested in its application. These teachers became the program evaluators and prototype testers. The teachers also provided case studies for possible inclusion in the program. Six program trials were conducted where teachers reviewed the content of the subjects, including related readings and other software resources provided by the project. The involvement of the teachers in this process was crucial as it provided excellent feedback on both the content and interface design of the program, for example, the identification of faults/errors, annoying or distracting sounds, and the modification of some structural elements. The helpful critique of the content meant that it could be made particularly applicable to the needs of classroom teachers. The teachers' overall assessment was one of approval and timeliness, and several indicated that they would like to have immediate access to the program to begin professional development with other members of staff in their school.

Accreditation Procedures

In order to qualify for the Graduate Certificate in Computer Education (Multimedia), teachers must complete and submit the assessment for all four subjects. For those not wishing to undertake the formal qualification, each of

BEST COPY AVAILABLE

the modules can be accessed separately, either for individual professional development or through professional development offered by educational consultants, professional associations or by staff within a school or cluster. The Queensland education authorities (state, private and Catholic) provide a certificate of completion to teachers who integrate components of the courseware into their teaching and submit a copy of their work certified by their school Principal. These certificates can be used to support applications for promotion or to receive credit towards the Graduate Certificate in Computer Education (Multimedia).

Enhancing Professional Development

The development of MITAC is timely as the integration of multimedia, as a teaching/learning tool, into classrooms at all levels of education is now increasing. The content not only provides educators with an understanding of how new technologies can be used to support student learning and teacher effectiveness, but also demystifies the new information technologies. MITAC is therefore utilising technology to demonstrate the most appropriate models for its application as well as providing a flexible twofold approach to learning options.

As technology changes, so too will the content of the subjects. MITAC will be updated on a regular basis, not only to maintain parity with current technology but also to ensure that the content continues to meet the needs of teachers. This serves to enhance the professional development of teachers because MITAC models best practice through the integration of flexible learning strategies with content which is both current and relevant to the target audience. Educators are exposed to a working example of the way in which technology can be applied both now and in the future, as well as providing them with access to a resource which has the potential to be a powerful and unique support for their teaching endeavours.

Building Partnerships

This project would not have been possible without the development of closer links between teachers, employing authorities, professional associations, and tertiary institutions with the aim of providing ongoing support for teachers. The facilitation of collaborative and collegial relationships between classroom teachers and university personnel, and the utilisation of a resource such as MITAC provides the kinds of structures and cultures both organisational and occupational which are compatible with the image of 'teacher as intellectual' as opposed to the 'teacher as technician'. It is to be hoped that such a partnership will encourage the integration of technology into the classroom and the ownership of professional development by teachers as well as their participation in postgraduate study.

For further information about the MITAC CD-ROM, please contact the author.

SINGING WITH SOFTWARE: THE USE OF COMPUTERS AND MUSIC IN EARLY CHILDHOOD VOCABULARY DEVELOPMENT

Abstract: This study examined an interactive educational computer program containing instructional lessons set to the music of a children's song titled, *"Oh I Want to be a Dog"*. The five stanzas of the song were illustrated with animation and integrated with interactive educational modules. The purpose of this study was to examine the impact of a computer program that employs music in conjunction with interactive activities to teach vocabulary words to Kindergarten age students. The sample group for the pilot testing consisted of eight students from a large Southwestern Elementary school. Results from the study indicate that music and interactivity found in a computer program have the potential to enhance vocabulary learning for young children. Both groups tested reported to have enjoyed the program, however the group exposed to the music reported to have learned more vocabulary words than the non-music group participants.

The value of books, artistic exercises, song and play in early childhood education are well documented. Teachers have incorporated these "fun" and engaging pedagogical techniques into their curriculum for quite some time. More recently, the availability of affordable computers presents educators with an additional tool for early childhood instruction. Computer research suggests that through the employment of computer-aided instruction (CAI), children discover the vast learning activities generated by computers (Shade & Watson, 1987). Indeed, previous studies demonstrate the effectiveness of music in education (Medina, 1990) and computers (Escobedo, 1992; Clements & Nastasi, 1993); *few if any report the use of instruction and music delivered on a computer.* There is a deficiency of research examining the impact of these two variables in tandem on vocabulary acquisition. This project presents a first step in filling this void in the literature. To do so, this paper, 1) addresses the benefits of combining CAI and music and 2) examines, through the field test of a program, "Oh I Want to be a Dog" how CAI and music improves the instruction of vocabulary for Kindergarten age students.

Interactivity, Music and CAI

Educators have found the dissemination of information via visual and oral stimuli to be as a powerful educational device. Stimuli from the audio channel (music) combined with stimuli from visual channel (graphics) present opportunities for increased learning outcomes (Schramm, 1973). When music is presented on a computer as an "interactive song" it has the potential to: 1) enhance children's expression of ideas by allowing the students to draw and manipulate symbols that represent action in the song, 2) improve children's understanding of the relationships between visual images and words and between spoken and written language, 3) increase children's interplay with sounds, rhythm and meaning of words inherent in songs and 4) fortifies children with access to multisensory learning.

As instructional tools, both music and CAI share common elements such as interactivity (although with different applications) and contain opportunities for vocabulary learning when used effectively. However, there is a gap in the amount of research pertaining to music and computer aided interactivity as simultaneous events in CAI. The purpose of this study is to find out if the use of music and CAI will enhance vocabulary learning as a result of using the program, "Oh, I Want to be a Dog". Thus, the following questions are advanced:

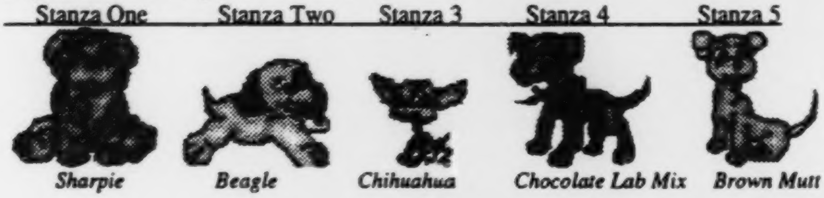
1. *How can the music and interactivity found in the computer program, "Oh I Want to be a Dog" enhance vocabulary learning for kindergarten children?*
2. *What are the student's perceptions and reactions toward the program?*

The Design of the Computer Program, "Oh I Want to be a Dog"

The song, *"Oh I Want to be a Dog"*, was written by Barry Louis Polisar. Charlotte Diamond, a popular Canadian children's performer, sings the lyrics. The composition of the song is divided into five stanzas and plays without a bridging chorus. Each stanza begins with the words, "Oh I want to be a dog" and continues to describe actions unique to that stanza. Among the actions are: a dog wagging its tail (stanza one) and a dog running after sticks (stanza four). The medium tempo of the song and the descriptive composition makes it easy for listeners to simulate the dog actions.

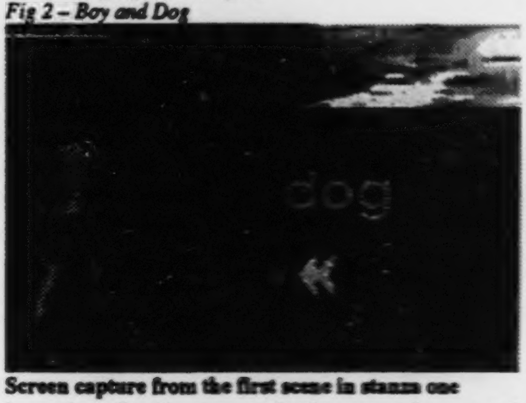
The *"Oh I Want to be a Dog"* program was created with the multimedia development software, Macromedia Director. Most of the graphics were drawn in Superpaint and imported into the program. The first screen seen gives the user a choice of either listening to the introduction, seeing the credits, clicking on the "dog check" dog which leads to the post-test section, or clicking on one of the five main character dogs. The five main character dogs are different for each stanza. They are, in order of the stanzas in which they appear (Fig.1).

(Fig 1) – Featured Dogs



When one of the dogs is clicked, the program opens to the stanza featuring that dog. Each of the five stanzas in the computer program contains three words chosen by the design team and author. These words are the "target" and are spelled out on screen during the music portion of the stanza. The target words are the specific vocabulary words for program users to learn. There are a total of fifteen target words for students to learn in the program. The format of each stanza remains consistent throughout the program, and yet the graphics and target words vary. Each stanza begins with lyrics "oh I want to be a dog," and describes the action taking place in that stanza. For example, as the word "dog" is sung, the word "dog" appears in textual form with an arrow pointing to the illustrated dog for identification purposes (Fig.2).

Fig 2 – Boy and Dog



Screen capture from the first scene in stanza one

Immediately after the music section of each stanza ends, the screen freezes and interactive buttons appear. At this point, students have the choice of either going to the interactive practice section, repeating the music portion, or going to the next music portion. The dog from the corresponding stanza is located in the middle of the screen while the target words form a semi-circle around the dog's head. When the student clicks on the word "dog", for example, the song lyrics, "oh I want to be a dog" are heard and the dog shakes its legs and head indicating that the word "dog" is part of the song and represents the animal on the screen. All five stanzas employ the equivalent format for the practice section, and display three target words chosen from the lyrics of the song.

Dog Check (Post-Test)

When students finished the last practice section, students were asked to play with the "Dog Check". The

BEST COPY AVAILABLE

"dog check" is composed of the fifteen target words from the program, as well as their graphical representations. Each screen hosts three words from different stanzas and their corresponding graphics to make a total of five screens. The object of the exercise in the "dog check" section to use the mouse to drag a graphic from the right side of the screen to the word it represents which is located on the left side of the screen. For example, the second screen of the "dog check" displays the words "moon", "wag", and "dig" on the left side and their graphical counterparts on the right side of the screen. The word "moon" and the picture of the moon are taken from stanza four, the word "wag" and the dog wagging its tail are from stanza one and the word "dig" and the dog digging are from stanza two. The "dog check" was designed so that the five different dogs featured in the program are paired with the target word from the same stanza the participants were exposed to during the music and practice portion of the program. It was used as a measurement to access vocabulary acquisition.

Software Design Considerations

There are many considerations incorporated in software design. When designing *"Oh I Want to be a Dog"*, the production team considered factors such as music, age appropriateness and multichannel learning as important design features in an effective and enjoyable program. These design considerations are discussed below.

Music. Music played two major roles in the design considerations for the computer program, *"Oh I Want to be a Dog"*: as a visual/animation guide and as a catalyst for motivation and social interaction. As a visual guide, music plays an identical role to that of narration in a story. Just as a storybook narrative guides the artist in illustrative decisions, lyrics dictate visual design. Computer program animation illustrates the song's words. For example, the dogs behave according to the lyric description of them. Also, the length of the "chapter" or stanza solely depends upon the tempo of the music. The break point in the stanzas is a natural lead in for the practice sections.

When music is simple, clear and easy to understand, it is effective at motivating the student to sing and enjoy himself or herself (Beaty & Tucker, 1987). The program, *"Oh I Want to be a Dog"*, utilized music's potential to engage and excite the listener. Music encourages students to sing together, make up musical stories and it provides an activity that can be shared by many. Students not only work together at the computer making decisions, but the program also grants an opportunity for voices to join together in song. When students are familiar with the song, they sign along with the software.

Age Appropriateness. The issue of "suitable materials" is important when designing software. Beaty and Tucker (1987) explain that "a developmental toy, ... should be challenging but not too difficult for a child. Some puzzles are too simple, some too complex" (p. 48). In order for software to be effective, it must be appropriate for the age of the child. It must take into account reading ability and motor skill functions.

One of the challenges in designing computer programs for young children is that they are not advanced readers and are unable to follow written directions. In the case of pre-literate youth, it is sensible to use text plus graphics. *"Oh I Want to be a Dog"* uses this technique throughout the program. The target words displayed during the music portion and practice section are accompanied with graphics that correspond to the text. When the dog runs on screen in the first stanza, the word "dog" appears on screen with an arrow pointing the to picture of the dog. Although kindergarten students cannot fully read, they begin to make the connection between words and pictures.

Another challenge to designing computer programs for young children is they require activities which do not demand extensive typing or advanced motor skills. Research found that young students show the greatest efficiency with a computer mouse instead of the joystick, and keyboard (Alloway, 1994). Therefore, the program *"Oh I Want to be a Dog"* was designed utilizing the mouse so young children could easily and readily use the medium. The mouse is the only device for interactive control.

Children need to control actively what the program does (Beaty & Tucker, 1987). Users of the program, *"Oh I Want to be a Dog"* have many control options in the practice and "dog check" sections. The practice sections allow users to click on the words in any order and multiple times. The "dog check" section encourages students to decide which word they want to drag with the mouse first, and where it belongs on the screen. Navigation buttons are also a source learner control. Users make constant choices on where they would like to go next in the program. They have a choice of either going to the home page, repeating the music, going to the next stanza or reviewing the target words in the practice sections.

Multimodal Learning. Songs can be audio-visual (as evident with music videos) and kinesthetic in their heart-felt beat as well as emotionally stimulating. The combination of computer programs and music provides all three sensory domains to promote a better chance for multiassociational encoding of information. All three sensory domains are utilized in the computer program, *"Oh I Want to be a Dog"*. Users see the actions on screen, hear the accompanying music and sway their bodies to the beat. The triple repetition of the target words via sound, graphics and text increase opportunities to learn new vocabulary.

Procedure

The students were visited two times. The first visit was for observational purposes and allowed the experimenter to assess the student's knowledge and enthusiasm toward computers in general. The researcher remained in the classroom approximately one half-hour and watched as the students worked on computer programs available to them. Also, a consent form was sent home to the parents.

Eight students were selected to participate in the study based on consent form return, availability and gender. During the second visit, the researcher set-up the *"Oh I Want to be a Dog"* software and called the participants to the computer, one at a time, to work with the program. The program was not available to the students prior to the researchers second visit to the classroom, therefore the students were not familiar with the program content or the song.

Before each participant began, the researcher explained the testing procedures and directions for using the computer program. There was no time limit each student could work on the program, but the length of time per individual session was recorded. After the participants viewed the music sections and practiced with the words from each stanza, the researcher instructed the participants to return to the home page to access the computer-based post-test, or the "dog check". The researcher gave students instructions on how to interact with this section and then recorded their actions. This procedure was repeated with each student for a total of eight individual sessions.

The researcher recorded how many attempts it took students to connect each picture to the text it represents. The participant received a perfect score of fifteen if they matched all fifteen words and pictures on their first attempt. Five was the lowest score possible because of the screen layout. If students got two of the three words on screen identified properly, the student matched the third word to the correct graphic because it was the only remaining choice. The data generated from the post-test was based on the number of times it took the students to get the correct answer on their first attempt at matching the graphic with the textual equivalent.

The researcher also asked the participants six basic questions in random order, in regard to user reaction to the program: 1) Were the instructions clear? 2) Was the program easy to use? 3) Did you like the pictures? 4) Did you learn new vocabulary after you used the program? Which ones? 5) Did you like the program? What did you like about it? and 6) Would you play with it again? Why? (Adapted from Shyu & Brown, 1992).

Results

The first research question to be answered was: How can music and interactivity found in the computer program, *"Oh I Want to be a Dog"* enhances vocabulary learning for kindergarten children? In order to determine if music and interactivity in a computer program can enhance vocabulary learning, the participants were divided into two groups to compare the results between exposure to music in a computer program and non-exposure to music in the computer program, *"Oh I Want to be a Dog"*.

Group 1 played with the program enhanced with music, but the sound was turned off for Group 2. There were four students in each group, two boys and two girls. Except for gender considerations, all students were placed in either Group 1 or Group 2 at random. There were no notable differences in academic level between participants in either group.

Overall, the students in Group 1 (music) scored higher on their first attempt at the "Dog Test", as well as their consecutive attempts at connecting the graphic to the word than did their non-music counterparts as displayed in *Table 1*.

Attempts	*Group 1 (music) Scores*	*Group 2 (no music)Scores*
1st attempt	48	28
2nd attempt	8	22
3rd attempt	4	10
TOTAL	60	60

***Table 1*: Five screens with three words per screen, students dragged the graphic to the word representing the graphic.**

In order to measure the success of the program, a t-test was conducted on the first attempt scores only. Using an independent samples t-test, it was found that in this field-test that music and interactivity has the potential to enhance vocabulary development ($t=3.425$, $p. < .05$).

Research question two explored the student perceptions and reactions toward the program. Students were asked to answer either "yes" or "no" to Questions 1, 2 and 3. All eight students responded "yes" to the first three questions and offered no further insights as to the clarity of the instructions, difficulty of the program and picture quality in these questions. Question 4 and 5 prompted more commentary and learner insight.

Student reponse to Question 4 - "What new words did you learn" varied between groups. In Group 1 (music) three students learned "jump", two learned "moon", and at least one said "dog", "human", "look", "run", "tail", and "wag". In Group 2 (no music), three students learned "jump", and at least one learned "dog", "human", and "wag". The students reponses were similar when they asked what they liked about the program: Group 1 liked music (4 students), practice with words (3 students), word test (3 students), graphics (2 students), dog actions and animation (2 students), sing with the music, and sing to remember words. Group 2 liked to practice with words (3 students), word test (2 students), graphics (3 students), dog actions and animation (3 students).

All students responded to question six (would you like to play with the program again) with an emphatic "yes". Two students from Group 1 wanted to play with it again at that moment because as they reported, they enjoyed the song and playing with the graphics and words. A student from Group 2 commented that it was fun and her family owns a dog.

Overall, the students did not differ in their enthusiasm toward the activities in the program. All of the students gave positive evaluations of the program. Group 1 had twice as many positive comments on the program as Group 2. Their comments focused on music, graphics and word practice while those in Group 2 were more interested in graphics and word practice. As results from the pilot testing indicate, the participants in Group 1 reported to have learned more vocabulary words than did the participants in Group 2, who were not exposed to music during the program.

Discussion

This investigation of the software program *"Oh I Want to be a Dog"* provided insight about the phenomena of music and interactivity in computer-aided instruction. The researcher found in this pilot testing that music and interactivity combined in CAI has the potential to enhance vocabulary learning in kindergarten children. Furthermore, results from the pilot testing indicate that the use of music in this computer program has the potential to enhance the vocabulary learning, as reported by the student participants.

Results from the t-test suggest potential responses to the first research question: How can music and interactivity found in the computer program, *"Oh I Want to be a Dog"* enhances vocabulary learning for young children. Specifically, results from Table 1 indicate that music and interactivity aids in the increase of a child's understanding of the relationship between visual and written words, spoken and written language. Groups 1 scored 33% higher than Group 2 and had a better average at getting the answer correct on their first attempt than Group 2. This finding suggests that music not only served to engage the user in the lesson, but also prompted them to pay closer attention to the target words and they were better equip to connect pictures with words in the post-test.

Table 2 reflects a notable difference between the words reportedly learned in Group 1 and 2. When asked question 4, what new words they learned, students in Group 1 reported learning 8 new words compared to the 4 words in Group 2. In addition, more words were mentioned multiple times from participants in Group 1 than participants in Group 2. Prior research supports this finding for music and extralinguistic learning (Medina, 1990). The words in a song may also provide oral support and meaning. The addition of music and rhythm helps verbal learning (Bottarri & Evans, 1982). Songs children sing can help them to learn new ideas and written words. During the test section, the researcher observed two students from Group 1 singing the song in an effort to connect the connection the lyrics with their graphical representations. Students used the music as a device to recall words and connect those words with the pictures they saw on screen. Additionally, research found that sensitivity to rhyme and along with it, the detection and production of rhyme and alliteration were related to phonological awareness to early reading skills (Bradley and Bryant 1983; Bradley & Bryant, 1985; Bryant, Bradley, Maclean & Crossland, 1989).

Questions 1, 2, 3, 5, and 6 in put forth responses to research question two, what are the student's perceptions and reactions toward the program? As stated in the results section, each student answered positively to a series of questions related to the instructions, ease and picture quality of the program (questions 1,2,3). The notable difference in the two groups is found in the answers to Question 5 and 6. The responses to Question 5 are a reflection of their group placement. It is no wonder that students in the Group 1 mentioned music as one of their favorite part of the program. It is fun, motivational and engaging. Children enjoy engaging in music when it is playful and they can respond to sounds and images (May, 1988). Through song games, children are motivated to work with letters and symbols (Richards, 1971). Groups 1 and 2 both mentioned that the practice sections and the test portion were "fun" while the graphic and animation were also mentioned favorites.

The most telling indication of motivation and enjoyment was revealed with Question 6. All students who participated in the study expressed a desire to play with the program again. Six students reported that they enjoyed the practice section. The practice section is interactive, designed to give the user control of the learning environment. Two students from Group 1 requested to play with it after their individual session was complete. Students who were in the classroom while to testing took place asked to play with the program, and commented on the bright graphics and active animation.

Part of the intrigue with the software is due to the novelty of a new product in the classroom. However, most of the credit for the success of the program is given to the music and interaction on screen. Early childhood students are extremely honest, if they did not like the program, they would have communicated this opinion. A student in Group 2 mentioned that she liked it because she likes dogs and she has a dog at home. This statement accounts for the age appropriateness of the program and keeping the scope of the project within the realm of understanding of the students. Students could identify with dogs and their behavior. Prior research supports this reflection by stating that music is effective with young children as it can reinforce what they already know (Bamberger, 1983).

Conclusion

Music represents an area where children can explore their creative sides such as playing with sound and rhythm. Children enjoy interesting sounds and often react positively to music reinforces. Furthermore, the music serves as a prompt for the planting the seeds of learning how to read. The best music programs are simple yet allow children to explore sounds, words and expand their imagination. The software *"Oh I Want to be a Dog"* fulfills these basic requirements by allowing students to use the music to explore sounds, graphics and develop their awareness of written words. Indeed, previous studies demonstrate the effectiveness of music and computers in education but few if any report the use of instruction and music delivered on a computer. This investigation provides insight for the potential of music and interactivity combined in a computer program to enhance vocabulary development.

Object Orientation in Discourse Structuring

Julean A. Simon
indep. researcher, Berlin
simon@berlin.snafu.de

Abstract: DisNet is an environment for structured communication and collaborative working, learning and playing suited for small work-groups. It conforms with the basic idea of hyper-systems in that it allows for representing context as a linked, nonlinear knowledge structure integrating multiple data types. Beyond that, "Discursive Networking" intends to organize collaborative learning and working as an open discourse and to represent the development-process of a context as a networking of contextual objects on the basis of their relations.
Contextual objects consist of a userdefinable set of relations - a frame - that describes several aspects of the object; it makes these aspects explicit and accessible. The strategy enhances hypertextuality to include multidimensional linking of objects and results in a "stratification of context". Object Orientation supports the creation, access and manipulation of these objects, in that it encapsulates data and methods; inheritance is employed on the formal as well as the contextual level. On the database-level objects are represented as tuples in a distributed tuplespace; the main methods are matching and compression (substitution by a reference).

The Hypertext Paradigm

The basic idea of inter-textuality, coined as "hypertext-paradigm", appears to be a considerable approach to nonlinear knowledge representation and a guiding principle in providing access to, and supporting the generation of context; in principle, the paradigm provides an appropriate basis also for networked collaboration. In practice, though, hypertext-implementations focus on the delivery of structured information and do not foster dynamic generation of context, and collaboration.
The ideological and market-economical reasons for this tendency are not discussed here. Another reason is implied by the node/link-principle itself, especially in its simplest form (as usually employed in hyper-systems). This simple formalism (see e.g. HyperCard) requires a consistent use of the formal elements throughout a hypertext and is therefore best suited for representing content that is homogeneous with regard to its type and characteristics, and that has a clear structure. This requirement can be met better by a single author than by a collaborating group. The need to formalize the content and to plan the structure favors the use of preproduced content material and positions most hypersystems in the domain of authoring, publishing and delivery tools.

Various solutions have been presented to overcome limitations on several levels. Some strategies build on top of an existing hypertext, using it as a scaffolding and provide write-access in allowing users to link annotations [Röscheisen, et.al: "Commentor"]; other systems enhance the hypertext organization and index the nodes to improve browsing and orientation. Other approaches enrich the formal infrastructure to anticipate contextual differentiation for example by providing several object-types, or a set of typed links [e.g. Conklin/Begeman 1988:"gIBIS", Bernstein: "MacEuclid"]. An important enhancement can be seen in the furnishing of objects with a set of attributes, as used for database-records [e.g. "Lincks"]. DisNet intends to apply the hypertext-paradigm to collaborative work, therefore several modifications to the original principle are proposed.

The Collaboration Model

DisNet stands for "Discursive networking" (the term includes a gerund to stress process rather than content, or connectivity); the model has been developed initially for educational use, where collaboration often has a discursive characteristics: given a topic, the field is explored by posing questions, forming and testing hypotheses. The participants contribute in a more or less informal manner and the teacher provides some guidance in keeping the discussion focused, hinting at important aspects and preserving a working atmosphere capable of integrating the students individuality and creativity. While current learning systems focus on retrieval, presentation and browsing of preproduced materials, learning is understood by newer learning theories rather as an effect of self-, or group-controlled activity in a problem-field.

Contributions to a discourse can be made on several contextual levels: we may distinguish between the discursive, the meta-discursive and the representational level. The discursive level concerns interactions with regard to the chosen topic; meta-discursive interactions regard formal and structural aspects of argumentation, working methods and strategies; the representational level concerns the configuration of the collaborative system, the representation of the work process and the knowledge organization it fosters. All of these aspects contribute to the context and should therefore be represented in the context space.

The standard relation between contributions in a discussion is established in that an argument refers to an argument which has been posed before. In a "round-table" discussion it often remains implicit which contribution an argument refers to and how it relates to it; this information is partially derived from the situation and the way an argument is presented. The current speaker continuously evaluates the reactions of the listener and seeks to correct misunderstandings immediately.

Especially in asynchronous, networked collaboration (which allows a participant to choose his or her own path through the network of argumentation) the intended linkage of an argument and its particular relation with another argument has to be made explicit by the author. Yet, the context is not only constituted by this argument as such, but is a multiple relationship (who said what, why, when,...). Depending on the intentions of the collaborators and the scope of a project a contextual component may be established by various relations, which may concern content-related, structural, methodical, strategical, organizational, representational, formal and functional aspects. At least the contextually most significant of these relations have to be made explicit in an asynchronous discourse, or collaboration and the collaborative environment (the context representation system) has to support this and represent the continuous differentiation of context with regard to these relations.

The Object Model

The constitutive elements of an object are usually called attributes, or properties. We speak of relations, because in DisNet objects are understood as inter-related contextual components. A relation is established and made explicit in terms of an attribute/value-pair, called "slot"; an object consists of a definable list of slots, which is called "frame". Thus the basic object in our model is the frame, which is treated as an object oriented data-structure. While in the traditional hypertext-concept the elementary objects are documents (nodes/cards) and references between them (links), in DisNet a contribution to the discourse and its relations to other contributions are values assigned to slots (argumentative multimedia material, relation-type, data-type, creation-time, title, abstract, keywords, status-flags, constraints, object-behavior, etc.). The formalism integrates an object's aspects; it deals with multiple relations (as we are used to in a "round-table" discussion).

The reason to use Object Orientation is not (as often, especially when applied metaphorically) to resemble a pseudo-materialistic "world of objects", rather it is used as in programming, as a formal scheme that encapsulates (descriptive) relations and methods (functional relations). There is no dominant constituent that represents an object; the object-characteristics emerges through the coordination of an objects internal and external relations.

The formalism establishes a formal relationship between objects and allows to generate new objects and object-schemes by differentiation of already defined objects, and it provides also a way to generalize methods for establishing, accessing, representing and manipulating object-relations and objects. While collaborative environments typically use task-, and application-specific knowledge-representation, DisNet employs Object Orientation to provide a general knowledge-representation formalism that can - with minor adaptation - be used in different application-fields.

When a new object is created it causes and represents a differentiation of the existing context it is linked with, and this differentiation is based on the contextual relations which the object makes explicit. An object is established in terms of its internal and external relations. The internal relations determine aspects such as: who said what, when, how, why...; the external relations of an object specify its connections and relations to other objects. This strategy establishes relations between objects on different levels and causes a "stratification of context".

The frame (slot-list) describes an object's relations; it provides comparable data-sets and makes contextual relations explicit - and thereby accessible. Usually, interactions in a collaboration are not easy to categorize. Forcing the user to fill out a form reduces the value of the data, because the slot-types may not always suit the object's characterization s/he has in mind. Describing an object often involves a redefinition of the categories of description. Therefore DisNet provides a userdefinable rather than a fixed set of slots: in order to make properties of a contextual component explicit the user may not only enter a slot-value but also (if necessary) define a new slot-type. In principle, a new frame-type may be defined for every object (this is not encouraged, the normal use case will manage with a few frame-types). Note, that the possible inefficiency of in-compatible frames is not necessarily an argument against this approach, because it might correctly reflect an "incompatibility" of contextual components, or disagreement among the collaborators in the categorization issue. Such problems should be addressed by the collaborators and not hidden in a rigorous formalism.

To minimize the accumulation of unrelated frame-types a new slot-type has to differentiate (override) an existing slot-type and a new frame-type (slot-set) is a modification of one defined before. By this strategy a flavor of object orientation is introduced on the discourse level, in that inheritance not only as usual propagates default-values, but formally relates contextual components. As far as useful and possible type-dependencies can be used to organize the internal structure of the frame (e.g. the relation between: title < abstract < fulltext suggest to let the title-slot of an object reference some term in the abstract, the abstract-slot some regions in the fulltext). Another technique is the reuse of object-parts, objects, or object-structures and the forming of new objects from existing objects.
The rule that a new object has to be created out of an existing object not only intends to prevent the project-space to be used as a container for vaguely related objects, but especially to contextually link an object to the reference object (insinuating a new object to be a differentiation of the referenced). This local rule is the engine that drives the generative and self-organizing collaborative process; it produces the network of contextual components.
Insofar as corresponding slot-values of objects are identical, related, or refer to each other, the slot-values of an object establish its external relations to other objects and therby specify the context. A context is determined by the history of its development which presents at any time a structure, based on the connections and relations of its components and thereby also sets the conditions for its further development.

A project initially consists of a seed-object that defines a generic frame (slot-list and the expected values as placeholders, or defaults). It may be linked with an object that contains the data and access-rights of collaborators and with an object that describes the compliance code (definition of the topic, working methods and strategies, system configuration). The initiator of the project may structure the project in advance (scaffolding) by positioning objects in the projectspace as linking-nodes for sub-topics (containers), or as templates that specify the methods to be used in the collaboration. Objects containing working material, or questions may be supplied to initiate and direct the working process.

Implementation Model

The core of the system is a database organized as a tuplespace [Gelernter 1985]. In particular it is a distributed (Linda Team), object-oriented [Eilbrecht 1995] tuplespace with a special instruction set (that provides a more direct interaction with the tuplespace and passes more control to the interface/user). The tuplespace may be distributed over several machines or media, and a local tuplespace (cache) is used by a client to minimize net-traffic. A tuple contains a reference to (a tuple that determines) the frame-type of the object and the corresponding slot-values (which may be references to other tuples). The main methods are matching and compression; compression means that redundant information is substituted by a reference.

The tuplespace model has been chosen to de-couple data from an address-based organization and to thereby allow the database to perform internal restructuring. Another reason is that a collaboration in many aspects resembles parallel processing. The tuplespace model is based on the orthogonality between creator and receiver, creation and usage: in the process of a collaboration the relation an object will have to its context at a certain time can not be determined in advance; the current "locality" (address) of an object is set by user-interactions via the interface and is therefore variable.

The modularized frame-structure reduces redundancies by reusing existing information grouped in sub-frames (e.g. containing logical, physical, temporal, personal, conver/sal, contextual, representational and processual data). It also reduces net-traffic by selective transfer ("on demand"), and by storing object-parts where they are needed (e.g. the representational sub-tuple containing the visual configuration and status-flags of an object are kept in the local tuplespace of a client).

A slot-value may contain a reference to another tuple, a valid input, or a placeholder (that describes the appropriate input, or its format), or it may contain a function (script). A general function of slots may be to parse and evaluate the input (format) provided by the user and reject inappropriate values, or notify the author.

The main operation in the tuplespace is matching. Subject to matching can be slotnames, or corresponding slotvalues (which can also be constraints). Search is performed by creating an object that specifies the particular search-values and -conditions, which subsequently places a tuple in the tuplespace and retrieves matching candidates. Search-, or filter-objects can be configured to find objects with particular properties, get an immediate or a future result (polling) and die after the result has been delivered, or can be installed in the tuplespace to permanently retrieve matching objects, or as (timestamped) questions to be answered by collaborators. When a new object is created the tuple-fields (slot-values) are matched against fields of existing tuples in order to prevent redundancy, or to notify the author of possibly related objects existing in the tuplespace. Objects in the local tuplespace (cache) are regularly matched against the corresponding objects in the global tuplespace to recognize updates. Defining the sequence of matching operations an object can be given a functionality that makes it behave like an agent.

A history-object collects the sequence of events; the type of events to be observed and the granularity can be determined. The history-object is used by a client to visualize past events (colorize visited objects); it can be edited and published and the client-functionality can be bound to its sequence of events (guided tour).

Interface: FRAMER and STRUCTOR

The user-interface is de-coupled from the database; this (Model-View-Controller paradigm) enables the user to simultaneously view and manipulate data graphically and textually. The interface is modularized, so in fact a module-family is provided for particular domains of interaction and may be combined. In the following, two of five currently specified domains of interaction will be described briefly (multimedia capabilities, context-sensitivity of menus, floating menus, etc. will be omitted):

The FRAMER is the object browser and -editor for displaying and editing slot-values of an object; it allows to browse through a project on the basis of relations between objects. The FRAMER-prototype consists of several fields and two popupmenus: one to select a slot from the slot-list, the other to choose the same slot in another object. A slot can be assigned to a field.

The STRUCTOR is an interface which graphically represents a project's object-structure. The structure can be represented in a 2D-, or 3D space (e.g. flow-diagram, cone-trees, spheres, topologies); objects are represented by graphical objects that carry a label and color-symbols representing relation-types; the user can determine the relations between objects to be visualized, e.g. as links. The representation space can be navigated, objects can be manipulated; clicking an object opens it in a Framer.

Other interfaces are provided, or can be build or configured from within the system (scripting); essentially an interface is represented by a configurable /scriptable object. The domains of interaction are coupled structurally, i.e. changes in one interface yield corresponding changes in the others; particular interactions with objects switch to a different interface, interface part or interface mode (context sensitivity).

Many multi-user environments are based on the postulate that all participants should at a particular site and time see the same data represented in the same way. Assigning priority to this kind of consistency favors a hard-wired, global worldview with the characteristics of a broadcasting medium. There are cases where global synchronization is appropriate and efficient, but in general we think that especially in asynchronous collaboration the controllability by the individual participant should be prioritized. Of course the system has to provide synchronization (data-update, data-visualization, views, functionality, system-configuration, etc.), but selective and on demand. "Synchronization on demand" is thought of as an exchange of a Compliance Code that contains information about the system state, configurations, conventions and rules, etc., on the basis of which the user, or the client decides what to synchronize.

Pedagogical Implications

The approach is in accordance with the "Projekt Methode", and with newer constructivist and sociocultural theories, in that it provides a collaborative, contextualized, knowledge-building and knowledge-using environment for learning.

The communicative structure supported by an educational network-environment has to be open to promote types of interaction that may generate the necessary collaborative dynamics; the underlying system has to establish this openness and provide transparency, configurability on several levels and adaptability to different tasks. Several dimensions of openness can be indicated to determine the structure of the domain of interaction: communicative openness implies the maxim, that all participants be equally and fully embedded in the information-flow (and are in control of this flow); operative openness allows the participants to configure the interfaces and devise the structure of communication and cooperation in a project; strategical openness is secured in that project-oriented methods and strategies may be discussed, dynamically established, or modified in a meta-discourse.

This form of collaborative learning can be typified as an open discourse. In this context a discourse is thought of as an iterative and (self)referential structure of interactions in a problem-field: it is an iterative process where new thoughts build upon previous ones, whereby a reference structure develops; and a discourse is self-referential in that the methods and strategies to be applied, its organization and scope are also made its subject (meta-discourse). The approach intends to extend the common understanding of networking as "collecting and redistributing information" towards a "collaborative generation of context".

Beyond the authority over the content the collaborators are given the responsibility for the organization and maintenance of the environment which intends to motivate a conscious and self-responsible participation.

The pedagogical goals aim at improving argumentative preciseness, acquisition of analytical and integrative competencies and developing awareness of knowledge-relations. We understand that a main feature catalyzing learning is the feedback between mutually stimulating interactions (such as orientation, interpretation, reuse, differentiation, extension, etc.)

Acknowledgments

The paper refers to the model of a collaborative environment, called "DisNet" which has been developed by [Simon, Wohlhart 1995] since 1994; it has been specified initially for an educational broadband-network project commissioned by the German Telekom and has been elaborated and reformed by the author [Simon 1996] since then.
The research has been supported partly by the Austrian Ministry for Science and Art.

Virtual Lectures for Undergraduate Teaching: Delivery Using RealAudio and the WWW

Alan F. Smeaton and Francis Crimmins
School of Computer Applications, Dublin City University
Glasnevin, Dublin 9, Ireland.
asmeaton@CompApp.DCU.ie

Abstract: In this paper we present details of how we delivered an undergraduate course in database systems to a group of over 100 students using RealAudio for audio synchronised with visual text, images and basic animations presented via the WWW. This electronic delivery of lectures was used as a replacement for the traditional mode and students could take these virtual lectures whenever they wanted, as often as they wanted and from wherever suited them. Our electronic courseware was organised so students could navigate through the material using a conventional table of contents, a back-of-the-book index we generated manually, or a search through the transcript of the audio dialogue. The paper discusses the benefits of organising course material in this way.

1. Introduction

The School of Computer Applications at Dublin City University is part of the Faculty of Computing and Mathematical Sciences and is responsible within the University for the subjects of computing and software engineering, as well as statistics and operations research. Our undergraduate degree program in computing, the B.Sc. in Computer Applications, has the largest enrolment of any honours degree program in computing in Ireland and has by far the highest demand for places of any computing degree in the country. Undergraduate computing facilities include a network of Pentium and P6 PCs with dual boot into either Windows NT or Solaris. Access is also available to UNIX servers and SUN workstations.

Because of Ireland's demographic distribution we have a large population of young people and an increasing demand for College education, especially in computing. Many large multi-national companies have set up manufacturing and distribution operations in Ireland as a base for Europe and the European Community and as a result the demand for higher level qualifications in computing has increased dramatically in recent years. This has resulted in increased class sizes leading to reduced personal contact between students and lecturers which is a bad thing. At present we admit about 150 students into the first year of our program annually, small by US standards but still the largest such program in Ireland. Selection of students is based on performance in state examinations and even with the numbers we admit we must still turn away bright and eager students who would gain entry in most other European countries.

"CA309: Databases" is a module taught to about 100 full-time and 20 part-time students in computing and 10 students in the B.Sc. in Applied Mathematical Sciences. These students are in the third year of a 4-year degree program. The course covers the basics of data modelling, the entity-relationship and relational models, database design and normalisation, SQL, an overview of some database products and some details on database implementation issues such as views, security, distributed databases and the system catalog. For many years the course had been taught using the traditional lecture mode of delivery with about 35 to 40 hours of lecturing, as well as laboratory assignments and an end-of-year written examination. The format for lectures was to use mass produced class materials and notes which were distributed to students, verbal elucidation of concepts by the lecturer using visual aids such as a blackboard as props, and animated explanation. This was backed up by two-way questioning between students and lecturer and informal discussion of the course at pre-arranged or ad hoc meetings.

Generalising, we can say that our educational format in this course had been typical of most University courses, a passive transfer of information via lectures with a re-enforcement of material in the library or laboratory using reference materials or exercises. With increasing class sizes and the pressure to take on even more students, even to double our intake, this trend away from student-lecturer contact was becoming even more pronounced. Such educational delivery has clear weaknesses in the area of personal contacts, distancing the student and lecturer because of numbers, and eroding the number and quality of one-on-one contacts and making most students reticent to approach lectures. In this paper we describe our implementation of a proposal to tackle this problem and we indicate the ways in which our proposal is being evaluated.

2. Using Computing Technology for Teaching

There are many ways in which computing technology can be used in education and in training such as the preparation of multimedia course material for distribution using CD-ROM. Indeed an industry of multimedia courseware production has grown up around this. Video conferencing using the internet is also becoming more and more common because of the cost factor and this can be used to deliver live lectures to remote locations. Although this has the advantage of being an interactive delivery of material, video delivery still has some drawbacks when it comes to users feeling involved with others via video links. It has been clearly shown that while computer-supported human-human interactions like attending lectures, mostly concentrates on supporting task-based activities, this is not complete without also incorporating a deliberate effort at replicating the social dimensions of human interactions such as chance encounters and group brainstorming [Bly *et al.*, 1993]. This has implications for our work.

The hottest development in using technology for education, however, is the use of the WWW for delivery of course material and student-tutor interaction and there are countless examples of such initiatives world-wide. The *World Lecture Hall* [World,1996] is an online repository or listing of such courses; and within the "Computer Science" classification there are already pointers to 94 courses in computer science on offer in various Universities, and computer science is just one off 98 such categories ! Most of these courses deliver teaching material organised as an electronic textbook or as electronic course notes which the student can "read" at his/her own pace. Some also provide multiple routes through the material, search facilities, integration of text, image, audio, video and interaction, and question-answer tests. For example, a series of "virtual" courses in Microbiology and Immunology have been jointly developed by the University of Rochester in NY state and the University of Leicester in the UK and like most such courses have resulted in the creation of electronically-available course notes. As the internet has had an increasing influence on our lives we see online course material emerging with links to other online resources like similar courses, online case studies, databases, etc. Besides the electronic provision of course material we can also find examples where technology is used to replace the classroom or lecture itself.

In our University, a course in database systems has been provided in hypermedia (text, image, audio) format since 1989. This started not as a set of online course notes but a collection of c.650 nodes of text/graphics information, woven together by hypertext links. Provided as a complement rather than a replacement for lectures, the course material was indexed and a method for dynamically generating a guided tour through the material in response to a student's query was developed [Guinan & Smeaton, 1992] To deliver this to students we developed our own hypermedia browser and evaluated this as a useful source of learning material during course revision using log files and questionnaires [Smeaton, 1991]. In 1993 the material was updated with more image and audio material and it was moved to the WWW where the guided tour mechanism was available and used primarily during course revision by students in our University and elsewhere.

What is common among the vast majority of cases of using computing for presenting course material that we have come across is that it is used either as an adjunct to traditional lectures or it is used to replace the classroom, or sometimes both [Marshall & Hurley, 1996]. Furthermore, material is organised as course notes, is low on multimedia and most importantly has not been evaluated as to its effectiveness in comparison to alternative modes of delivery. Our own efforts in this field over recent years via the guided tour navigation mechanism also fall into this generalisation. While such use of technology to present material in new ways seems to be scaleable to higher number of students technologically, in practice the higher numbers of students we are experiencing introduces new problems because we use lectures as the primary delivery mechanism to these increasing class sizes. At Dublin City University we have implemented what we believe to be at least a part solution to this issue through a series of virtual lectures and the remainder of the paper outlines the philosophy of our approach, describes its implementation and an evaluation of its effectiveness.

3. Background to Virtual Lectures

In order to address some of the problems of increasing class sizes our proposal was to use computing resources to create *virtual lectures* and to deliver material to students electronically. This is not the electronic classroom but using computers to deliver the lecture, the first time presentation and explanation of material. In effect we are creating the environment of a personal lecturer, whose voice, diagrams and sketches as drawn on a blackboard, whose animated explanations of topics, and whose course texts are delivered on screen for personalized, tailored delivery. This allows progression through material in a course as fast or as slow as the student wants to go and in an order or sequence driven by the student but guided and recommended by the lecturer. Thus the normal one-to-many lecture with its problems of class size and decreased personal contact is effectively given one-to-one, repeatedly as desired by the student. In addition to following a recommended path through the material yet with the freedom to re-visit segments of previous "lectures" to clarify aspects, to remind oneself of points or to test comprehension of topics, these "virtual lectures" are blended with tutorial sessions, more than is normally made available to students at this level, where students clarify unclear topics and follow set exercises to ensure their grasp of the material.

The tutorial sessions where students meet the lecturer to discuss course material, follow set exercises and clarify course content, are an essential part of our project. It is important for us to address the social consequences of students not attending class as part of a large group and we do this with group tutorial sessions which provide an opportunity for socialising, brainstorming and chance conversations. Because the databases course is one of 6 subjects taken by students where the other subjects are delivered in traditional mode we are confident students do not feel isolated..

The obvious benefits that a series of virtual lectures have are that students take control of their own learning and do so at their own rate, albeit moderated by the lecturer in charge of the course. The passive transfer of information as conventional lectures have become in times of large class sizes is replaced by personalized delivery, with the student determining when, what, how fast, how much and how often material is covered. The re-enforcement of material in tutorials leads to a broader skills base with students working better during tutorial sessions. In our mode of delivery, tutorials assume a more important and central role than otherwise as they become the major point of contact among students and between students and lecturer.

In defining the mode of delivery we now call virtual lectures it was important for us to replicate the lecture mode of delivery as closely as possible so as to minimise the culture shock students experience in moving from group participation in one-to-many classes to individual and user-controlled participation with virtual lectures. Our own experiences with making a hypermedia version of our course available to students over the last 7 years has been mixed with only some students really embracing the technology. This was partly because it was new technology but partly because people are not always comfortable with only a hypertextual organisation of material [Smeaton, 1991] despite the supposed advantages hypertext organisation has of user control [Marshall & Hurley, 1996].

Before we present details of our implementation there were some compelling reasons why we chose the course on databases as given to third year computing students, for this work. One reason was that these students were already quite familiar with Netscape and the WWW and so had no learning curve to climb in using the delivery tools. Also, these students already had a computing culture with the use of PCs on an individual or pairwise basis being an integral part of their daily lives. This is not so true for subjects in science, business or humanities subjects at our University. Finally, the School which is responsible for presenting this course already had the networking infrastructure in place, PCs with soundcards to deliver the material, and the technical expertise from previous projects to create, update and maintain the material as well as maintain the WWW and RealAudio servers.

4. Details of our Implementation

The contents of the database course have been re-organised into a series of segments or topic points. In traditional lecture mode of delivery, each of these would be an audio presentation synchronised with some visual props and question-answering with students. To replicate this closely, each segment is presented as a RealAudio track of between 2 and 20 minutes in length. Because we use a RealAudio server and RealAudio players on multiple platforms we can synchronise the presentation of material on Netscape or other WWW browsers using specification files as input into the server which detail when URLs, corresponding to visual material, are to appear in the user's WWW browser during audio playback. During playback users may also pause their virtual lecture to transcribe, take notes, rewind etc., using their paper copy of the screendumps which have been distributed to them. The set of segments comprising the course have been gathered into chapter-sized units for easier navigation. Each student has his/her own unique login identifier to the course material and on login are taken to the latest news of assignment deadlines, new materials online, place and time of tutorials, exam results.

Students are free to browse the material in any order using one of 4 navigation ways:

1. There is a complete hierarchical table of contents for the course and the lecturer recommends a progress rate through the material using this. This organisation is close to what is done in traditional lectures, moving from topic to topic within the hierarchy and for each topic playing the RealAudio segment.
2. There is a comprehensive topic index, like a back of the book index, with for each entry, multiple pointers to offsets within RealAudio segments for a topic. On clicking these offsets, the user is taken to just before the offset within the RealAudio track where the instance of the topic is covered.
3. We have generated a full transcript of the complete audio track, removed stopwords and stemmed remaining words and from this we provide a search facility for segments of audio. We have divided the audio tracks into 30 second segments, overlapping by 10 seconds and appearing like a sliding window through the audio. We treat each segment as a retrievable unit with higher weights for words in the middle of each 30-second segment. The search is implemented using a search engine developed in our Multimedia Information Retrieval research group [Smeaton &Kelledy, 1996]. The result of a search is a list of 30-second segments for the user to chose 1 or more to play. This is useful at revision time or when students are forming an overall picture of the course.
4. The visual material appearing onscreen is HTML and contains hypertext links to other parts of the course. Thus, for example, the text on-screen for a description of the SELECT operator in the relational algebra includes the following: "... this is not the same as the SELECT statement in SQL ..." with SELECT being an anchor for a link to that topic and SQL being a link to that topic. This allows students to browse through the material using the web of hypertext links.

The audio we use has been digitised using Cool Edit! sampled at 22KHz in monophonic format and saved in 16 bits WAV format. It is then encoded in RealAudio 14.4 format which we use instead of 28.8 because 14.4 has been optimised for speech. The audio is made available as a stream from our RealAudio server running on a SUN Ultra Enterprise 2 server on which our WWW server for the course material also runs. The networking and computing power of this set-up would allow us to handle much more than our current maximum of 50 simultaneous users. Needless to say there is a consistent user interface for screens with feedback and comments, next, previous, home, table of contents, index and search buttons always onscreen.

To reduce disruption in computing laboratories caused by audio over speakers, each student has been issued with a set of walkman-style headphones. All user interactions are logged for subsequent analysis. We had initially planned to use Java applets for animation in the course but have found that when we want to illustrate this then multiple GIF overlays in GIF89a format is adequate for our needs.

5. Analysis

The virtual lectures for CA309: Databases has been operational since the end of September 1996, with almost 150 students using the system as their mode of delivery for this course. Rather than being a technically-driven initiative, we include a considerable element of evaluation in our work. Students have completed a pre-course questionnaire in order to determine their familiarity with WWW and RealAudio, as well as their preferred locations for accessing the system. As each student is issued with a unique login identifier, all student interactions are logged and timestamped, on a per user basis, allowing detailed analysis of usage. Finally, students must participate in 6 or 7-person focus group interviews coupled with post-course questionnaires, both anonymous and named, in order to gain insight into what they thought of the system. The focus group meetings last 30 minutes and follow a hidden agenda of questions to be discussed in order to elicit students' opinions on aspects of the virtual lectures mentioned below.

When considering how to analyse our virtual lectures there are 3 aspects we must consider in parallel, namely:

- The performance of students
- The usability of the system
- The scale of investment needed to create and maintain virtual lectures

The performance of students is a measure of how well they have learned from virtual vs. traditional mode of lecture delivery. The obvious metric is performance in examinations but this is inadequate because there are so many variables to be considered, the learning ability of classes from one year to another, the relative difficulty of exam papers, etc. The opinions of the external examiners, whose role in our University is to ensure quality standards in teaching and in student performance are adhered to, will be included here, but we feel that there is little more we can do for this aspect of evaluating virtual lectures.

The usability of a system can be measured based on 5 criteria, according to [Nielsen, 1993] as outlined below.

1. Learnability refers to the user's ability to quickly learn how to use a system. In our case we measured how familiar students are with WWW and browsers and RealAudio before the course commenced, and in post-course focus groups and questionnaires we measure how quickly students learned how to use the index, search, table of contents, etc.
2. Efficiency of use in our case can be quantified by computing the amount of time spent by students using virtual lectures vs. the time they would have had to spend in traditional lectures. We have found that material is much more concentrated when presented virtually and as a result we suspect students may need to re-take parts of lectures to improve their comprehension, and on balance the amount of time spent in both modes of delivery might be equal.
3. Memorability is a measure of student's ability to grasp material quickly and to quantify this we can determine from log files and questionnaires, how much revision of the online material was taken.
4. Errors refer to the number of minor corrections (typos, HTML formatting, etc.) and major problems (system downtime, system failures) and this can be counted from log files and from user feedback.
5. Subjective satisfaction with the virtual lectures will be measured using post-course questionnaires containing Likert scales and semantic differentials for the major features in our system.

As we can see, for each of Nielsen's usability criteria we do have some kind of evaluation mechanism in place.

The final aspect of the evaluation of our work concerns the scale of investment needed to create and maintain virtual lectures. A material investment in equipment was needed for things like the machine on which the WWW and RealAudio servers run, the RealAudio server itself as well as other software for creating graphics for example, and the purchase of headphones for students. All of these have proved to be useful for other teaching activities; the lectures for a final year undergraduate course on multimedia systems is being digitised and made available on the equipment obtained for the virtual lectures project.

The big investment in creating the virtual lectures has been the time required. One full-time research assistant worked for 9 months on this project, setting up the servers, marking up the HTML, setting up and maintaining student accounts, troubleshooting, evaluating log files, conducting and analysing questionnaires, etc. The lecturer was also required to put in more effort for the virtual lecture delivery than for a traditional mode. On the plus side, the virtual lectures are now in place and re-usable for next year's teaching of the Database course, but would probably require revision and update after that.

6. Conclusions

The conclusions from the work we have reported here remain a little bit unknown; we don't know whether the way in which we have implemented virtual lectures works. What we do know is that the technical challenges have been overcome, in its operation the course delivery works smoothly but it remains to be seen whether the students have learned the material and how they regard the usability and effectiveness of the system.

There are some other points worth mentioning as conclusions for our work. In order for the virtual lecture to work, the course for which it would be used should not be a first year course as students would still be familiarising themselves with the computing environment. Furthermore, it should not be a final year course as these tend to be more interactive and are critical to a student's final degree classification. CA309 was ideal for virtual lectures as the topics covered remain fairly static over a few years and do not require major overhaul and update on a regular basis so we are happy that we chose the right course for this.

Our virtual lectures are not what is called distance education, though the technology we use can be used for that. We maintain close contact with students who work together in groups on campus as but whether our mode of virtual lecture delivery could be used for distance education courses is not something we address.

Finally, would we repeat the exercise of providing virtual lectures again, for other courses ? Certainly we have fully grasped the technology for doing this and were we to repeat it we could complete the task in less time than the first time took. While the investment in technology to deliver virtual lectures is becoming less of a requirement, the manpower effort required remains considerable and is considerably more than for delivering a course traditionally. Some of this investment is paid back when multiple runnings of a module use the same virtual lectures but with the cost of updating virtual lectures and personal interaction with students still required, delivering virtual lectures the way we do is not a cheaper alternative to traditional course delivery. Our virtual lectures are useful because of the multiple ways students have to access lecture material online at times that suit the students and not because they are a cost-reduction exercise for the University.

Abstract: We have started a project of making remote control system for a telescope in a public observatory in Japan. A remote client user can put in the celestial position of a target by the web home page of the system, and the telescope catches the target. The main purpose of this system is to show real time images to remote students for education. This system suggests CAGIS (Computer Assisted Guidance and Instruction System), which distinguishes this system from other remote control systems. If this system is used from high schools in western countries such as Europe or U.S.A., the students can see real time images of celestial bodies and celestial phenomena in the school hours. If this system is used from southern countries such as Australia, the students can see northern celestial bodies that is never seen from those countries. Therefore this system will contribute science education internationally. We are developing this system now, so it is not completed yet. In this paper, we describe concept and architecture of our remote control system of telescope with CAGIS.

1. Introduction

Recently in Japan, attractive science education is necessary for students, since many high school students don't want to study science. One of the largest reason of it, is that the lectures of science in high schools are not interesting, because they are only inputs of knowledge by text books without observation of real objects.

In this situation, celestial phenomena and celestial bodies seem to be prominently attractive, especially for young generation, because many planetariums and public observatories are always crowded with young generation. Although astronomy is a part of earth science in the curriculum of Japanese high school, it is not educated enough. Because it is impossible to show real celestial phenomena and celestial bodies to students in school hours, since most celestial phenomena and celestial bodies are seen in the night sky. On the other hand, these ten years, a lot of public astronomical observatories are established in Japan, and the total number of them is around two hundreds. Around fifty observatories among them have telescopes of more than 0.5-m, and four of them have telescopes of more than 1.0-m. Misato observatory in Wakayama prefecture in Japan has 1.05-m telescope, that is the largest one among Japanese public telescopes. On the other hand, only two public observatories in Japan connected to Internet by digital leased lines. Misato observatory is the first one among those two observatories. Misato observatory and Wakayama University have already been cooperating to try some new attempts for education by Internet and video conference tool[Watanabe et. al.1996a, 96b].

In these environments, we have started the new project to make remote control system of the telescope by using WWW for educational use. In this project, we prepare five servers, web server, telescope server, telescope camera server, wide view video camera server, and CAGIS (Computer Assisted Guidance and Instruction System) server. Remote client students access the web server, and get home page of remote telescope project. The student can select a target in a pop up menu, or can put in the celestial position of a target. Then the web server transfers the position to the telescope server. Then the telescope server moves the telescope to the direction of the target. A video CCD camera is set on the telescope. After getting real time image of the target by the CCD camera through the telescope, the image is transferred to telescope camera server. The telescope camera server transfers the image to the client student.

There are some other remote control systems of telescope for astronomical research use. The Berkeley Automatic Imaging Telescope (BAIT) by M.W. Richmond, R.R.Treffers, and A.V.Filippenko, is the system that performs all its tasks with minimal human intervention[Richmond et. al. 1993]. Colgate S. and his group in New Mexico Tech developed a system for Digitized Astronomy Supernova Search[Colgate et. al. 1982]. Smith C.K., Muller R., Pennypacker C., and their group in Lawrence Berkeley Laboratory also developed a Supernova Search telescope[Smith et. al. 1988][Perlmutter et. al. 1990]. Tosti G., Pascoloni S., and Fiorucci M. in the Perugia University developed the Automatic Imaging Telescope (AIT) using existing 0.4-m telescope with autoguider[Tosti et. al. 1996]. The purpose of these systems is to reduce astronomers' load. Astronomers can drive the telescope from remote room with comfortable environment. In the supernova search, for instance, astronomers only have to put in some job schedule of getting images of the sky by CCD camera, then the telescope system executes the job automatically.

On the other hand, a few remote telescope systems began to be made for educational use. Especially, Mar J.Cox and John E. F. Baruch in University of Bradford have developed excellent system that can be used on WWW[Cox et. al. 1994]. However their system attaches greater importance to technology of full-remote control than to education system. Also, their thesis is lacking in consideration how to apply the remote telescope to education. A part of our system is similar to their system in the architecture of remote control with WWW, but our system suggests to combine the remote telescope system with CAGIS (Computer Assisted Guidance and Instruction System).

In this paper, we describe the concept of our remote telescope project, architecture of our remote control system, and CAGIS. We are developing this system now, so it is not completed yet. When this project is finished, the telescope can be controlled from all over the world, When Japan is at night, foreign countries such as USA. or Europe is in the daytime. Therefore those who live in the countries can see real time image of celestial bodies at the daytime. This remote telescope system can be used at schools to teach science, and can be used in the planetariums for visitors in the daytime in the foreign countries. This global idea is proposed by some projects of remote telescope for education use, such as HOU (Hands On Universe) project[1]. Also, from southern countries such as Australia and South Africa, they can see the real time images of celestial bodies in northern sky, which is never seen from those countries. So this project will contribute science education internationally.

Figure 1: The architecture of the remote control system of the telescope with CAGIS

In this paper, we finally describe how to apply the remote control system to education. Also, we expect that students will be interested in not only astronomy and science but also Internet, WWW and computer science. HOU project and TIE (Telescope In Education) project[1] also make some science program combining astronomy and engineering. We also think that it is possible to make original combined curriculum of astronomy and computer science with this remote telescope in Japan.

2. User Interface by Web Page and Mechanism of Moving Telescope

[Fig.1] shows the architecture of the remote control system of the telescope with CAGIS. The user interface is made by web page with HTML on the web server, and it has pop up menu to select a target, and some blank to put in celestial position of the target. A student selects a target, or puts in the position of the target that he/she wants to see. This position is described by equatorial coordinates. Then the position is transferred to the web server, and a CGI (Common Gateway Interface) program in the web server gets the position. The CGI program calculates the sidereal time, by the Japan standard time, latitude and longitude of the observatory. Then the CGI program transforms the position of the target on equatorial coordinates into horizontal coordinates. If the altitude of the target is more than 20 degrees, the object can be seen in the sky clearly. If the altitude is less than 20 degrees, the object is seen low in the sky or cannot be seen because it is under horizon. In this case, the CGI program replies a message "The target celestial body cannot be seen, because it is too low in the sky or under horizon" to the student. Even if the target is seen lower in the sky, it is dangerous to move telescope towards such a target, since there is possibility that the telescope crashes into objects in the dome.

If the target is seen in the sky at the safe direction for the telescope, the CGI program transfers the position of the target to the telescope server. The telescope server calculates the difference between the position of the target and the current direction of the telescope. Then the telescope server sends necessary serial signals to the control module of the telescope. Finally the telescope is moved toward the direction of the target.

3. Video CCD Camera and Wide View CCD Camera

A video CCD camera is set on the eyepiece of the telescope. If the target is very bright one, such as the moon, Jupiter, or Saturn, the video CCD camera is enough to get the real time image. If the target is not bright one, such as a galaxy, nebula, and cluster of stars, an image intensifier is necessary between the eyepiece and the video CCD camera. By this composition, real time images of famous galaxies, nebulas, and clusters of stars in Messier catalogue can be gotten.

The real time image of the target is sent to the telescope camera server. Then the real time image is sent to the remote client student by a video conference tool such as CU-SeeMee. If the image on the client is too exposed or less exposed, the student can change the exposure from the web home page of the remote control system.

On the other hand, wide view video camera is prepared for getting real time image of inside of the dome. It catches the real time image of which the telescope is moving according to the student's request. The wide view video camera is also used to see weather condition of the sky. It shows where the sky is clear, or where the sky is clouded. The real time image of the wide view camera is sent to remote client student also by a video conference tool such as CU-SeeMee.

4. CAGIS

In the domain of celestial bodies, the position of the target on the equatorial coordinates is decided uniquely by the time and date. On the other hand, the direction of the telescope on the equatorial coordinates is easily calculated. Therefore it is easy to know where the student is observing in the target. By these things, it is possible to make CAGIS (Computer Assisted Guidance and Instruction System) for the student. Here we explain the mechanism of the CAGIS, using observation of the Moon as an example.

[Fig.2] shows the mechanism of CAGIS. It has two knowledge bases, domain knowledge base and operation guidance knowledge base. Domain knowledge base has many frames. Every frame has every domain knowledge. In case of the moon, domain knowledge is explanation of every part of the Moon, such as a crater and mare of the moon. A frame consists of three items. The first item is the location of the part on the selenographic coordinates. The second item is the name of the part, such as a name of specific crater or specific mare on the moon. The last item is the explanation of the part. In case of a crater, it is diameter, height of the rim of the crater, and origin of the crater.

The location of the part on the selenographic coordinates is used as a key to select adaptive frame from the domain knowledge base. How to select adaptive frame is as follows. Suppose that the student is observing a part of the moon. At the first, CAGIS transforms the direction of the telescope on the equatorial coordinates into the selenographic coordinates. Then CAGIS retrieves the frame which location is the same as or close to the direction of the telescope. After that, CAGIS calculates the age of the moon, and decide whether the part of the moon is bright or not. If the part is bright, CAGIS show the name and explanation of the part to the student. If not, CAGIS does not show them.

On the other hand, operation guidance knowledge base also has many frames. Every frame has operation guid-

5. Conclusion

In this paper, we described the concept and architecture of our remote control system of a telescope with CAGIS on WWW. The purpose of our system is education use. Therefor the system does not need to realize full-remote control, although a telescope for research use needs it. In the full-remote control system for research use, dome is also controlled from remote site, but it is not so necessary for education use. The main reason why we try to realize remote control, is to increase student's feeling as "using telescope by oneself", and to increase student's interest. Only a part of the celestial body is observed at a moment by a high magnification, if the celestial body is large, such as the moon, Andromeda galaxy, or Orion's nebula. In such a case, it is important that the student can control the telescope according to his/her desire, since the remote control brings him/her the feeling of voyaging in the space.

CAGIS helps such a voyage. On the other hand, if a staff is in the dome, it is possible to move the telescope by the staff according to the request from a student by phone call or e-mail. However this kind of system is not so interesting for the student, since it has less interactive feeling.

It is desirable that remote telescopes for education exist as many as possible in all over the world, because weather condition is not always good in one observatory. If there are many remote telescopes, some of them can catch the target in a good weather condition. For another reason, the view of celestial phenomena by the moon, is dependent on the location on the earth. For instance, a total solar eclipse can be seen in a narrow zone where the umbra by the moon passes on the earth. In neighbor area of the zone, partial eclipse can be seen. Therefore, if there are many remote telescopes on the earth, from an observatory in the zone of totality, the real time image of total solar eclipse can be sent to remote clients. On the other hand, from another observatory in neighbor area of the zone, the real time image of partial eclipse can be sent. If a remote client student receives some real time images from some observatories on the world, he/she can understand the difference of view of the eclipse. Also he/she can understand the umbra and penumbra passes on the earth as tume passes.

Eclipse of the sun is quite rare phenomenon, but occultation of stars by the moon can be often seen. As well as the eclipse of the sun, the view of occultation of a star depends on the location of the observatory. The point and time of disappearance and reappearance of the star against the moon differ according to the location of the observatory. Therefore if a student compares some real time images of occultation of the star from some different observatories, he/she can understand and measure parallax of the moon. By the parallax, it is possible to make an education program to calculate the distance between the earth and the moon. This kind of education program is a desirable science program. Because it includes observation phase of real objects and consideration phase of the observation. It enhances ability of observation of real objects and ability of consideration and study.

CAGIS is our original idea, that gives some explanations and guidance of the target. It helps the student to drive the telescope, and gives some useful information. It is also possible to put in questions instead of explanations in the domain knowledge frame. In this case, CAGIS become another type of CAI system, that consists of questions and answers. It will be an excellent CAI system that utilizes real time image as teaching material. It is our future work.

email:{stern, steinber, hilee, jitu, kurose}@cs.umass.edu

Abstract

The MANIC project in the Department of Computer Science at the University of Massachusetts is aimed towards facilitating individualized asynchronous distance learning. We take advantage of current technology, such as the World Wide Web and high-speed networks, to present a rich combination of text, graphics, and sound. We use student modeling to aid in the presentation of the material, including individualizing the instruction for each student and reducing the delays by predicting what the student will see next. In this paper, we present the initial work on the MANIC system and discuss the future possibilities and research.

1 Introduction

With rapid advances in telecommunication technology, distance learning is fast becoming a viable adjunct to the standard classroom model of learning and teaching. The MANIC project is an attempt to harness the power of general purpose computers (e.g., web servers), networking technologies (e.g., the Internet and higher-speed local area networks), and information presentation tools (such as WWW browsers and multimedia browser plug-ins) to create an asynchronous multimedia learning environment. Specifically, we are exploring how to most effectively use WWW multimedia technology (HTML and audio/video browser plugins such as RealAudio together with customized WWW servers) to deliver stored course or training materials such as class notes/overheads and audio/video of classroom lectures to students.

There are two ways of presenting educational material on the web: synchronous and asynchronous. Synchronous distance learning environments focus on creating an illusion of a classroom. This includes the delivery of live classroom lectures via satellite channels and video recordings of live classroom presentations. Internet-based conferencing tools have also been used to create live, networked distributed "classrooms" [Liebeherr et al. 96]. On the other hand, asynchronous systems are designed to allow students to use the software at any time, without simulating a classroom. With these systems, students proceed at their own pace and are not assumed to be accessing the same material at the same time as others. The goal of these systems, such as the system described in [Rebelsky 96], is to serve as an easy-to-access repository of reference material.

Our focus in MANIC is also on *asynchronous* learning environments, so students can access the software at any time without regard to others also using the software. Thus, while the synchronous distance learning approach attempts to recreate the classroom by connecting together distributed participants in real-time, our focus is on delivering *stored* multimedia materials and past classroom activities to distant students.

Given our focus on asynchronous student access, the goals of the MANIC project are threefold. The first goal is to develop *effective* WWW-based stored materials and presentation paradigms – to learn what does, and does not, work well by implementation and experimentation. Because we assume that a "live" instructor is not on-line with the student, our second goal is to develop student modeling and intelligent tutoring capabilities that allows the software to interactively guide a student through the stored material, providing individually tailored instruction for each student. The third goal of the

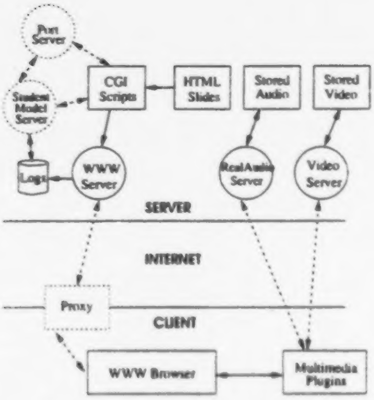

Figure 1: MANIC structure

project is to use MANIC as a testbed for research in the areas of multimedia networking and operating systems. In this paper, we focus our discussion on the first two goals.

In this paper we describe our initial efforts in constructing MANIC, focusing on both the software and the course materials we have developed. We also discuss the various larger lessons we have learned thus far. Although the MANIC project is still under development, a preliminary version of the system was used in a for-credit course being offered in the Fall of 1996 at the University of Massachusetts (`http://www-aml.cs.umass.edu/~amldemo/`), with additional courses currently using MANIC software in Spring of 1997 (`http://www-aml.cs.umass.edu/~cs653/`). Since the courses were taught in the VIP studios, we were provided with professional-quality recorded audio and video of the live classroom activities, which were then digitized.

The remainder of this paper is structured as follows. Section 2 overviews the hardware and software components of MANIC, as well as how course materials used for MANIC are created. Section 3 describes the various student-oriented features that we have built into MANIC and discusses their implementation. Section 4 describes future plans for the project. Section 5 concludes the paper.

2 MANIC: multimedia, asynchronous, networked individualized courseware

Currently, MANIC delivers text (HTML documents and still GIF images) synchronized with audio (encoded and delivered using a RealAudio server) over the Internet to students with multimedia capable machines with WWW browsers. This architecture provides for a traditional classroom like learning experience (unlike [Rebelsky 96]), but also allows for asynchronous learning (unlike [Liebeherr et al. 96]). RealAudio codes audio for potential delivery over 28.8Kbps dialup lines and hence MANIC course materials can be accessed at home, at school, or at work. Our design also has provisions for a video server (MPEG) to be added as well, and we are currently adding this functionality. In this section we first overview the MANIC hardware and software components.

MANIC makes classroom materials, including the HTML of the instructor's class notes (overheads provided by the instructor), classroom audio and classroom video available to students over the WWW. Initially, the notes we used were exact duplicates of the paper notes (specifically, a copy of the class overheads used by the instructor) used by in-class students. However, we soon realized that the on-line notes could (and should) be augmented with embedded hyperlinks to related material.

The course that we have already made available on-line via MANIC is a six-hour course on UNIX Network Programming (that was taught by J. Kurose in May 1996 in the studios of the Video Instructional Program (VIP) at the University of Massachusetts and distributed via the National Technological University).

The MANIC architecture is shown in Figure 1. On the server side, MANIC is built around a standard WWW server, with customized common gateway interface (CGI) scripts that generate, "on the fly", the

BEST COPY AVAILABLE

HTML document to be sent to the client. As we will see shortly, the ability to generate/customize a document on the fly allows the server to dynamically and individually tailor a document for an individual student. Currently, our primary use of this tailoring is to highlight selected portions of a document in synchrony with the audio.

The client accesses the course material using a WWW browser (such as Netscape Navigator or Internet Explorer) and the RealAudio and other multimedia plugins. The WWW server sends HTML text to the client browser. An audio stream is also sent to the client plugin by our separate RealAudio server. Audio playout and HTML presentation are synchronized and controlled at the client computer using the synchronized multimedia feature provided by the RealAudio server/player. In this paper, we will not discuss the intricacies of the multimedia synchronization mechanism nor the HTML interface programming required to integrate control of HTML and audio together in the browser's display; the interested reader is referred to [Kurose et al. 96].

The client-side components of MANIC are all "off the shelf" pieces of software. Indeed, one of our design criteria in building MANIC was that we *not* develop specialized client-side software beyond some simple Javascript programs. Instead, we leveraged WWW browser and plug-ins (such as the RealAudio client, which is available from RealAudio as a free download) as much as possible. This not only minimized our own software development effort, but aided in portability as well – companies that make browsers and plug-ins naturally want to make their products available on as many platforms as possible. Using off-the-shelf client software allows any student with a multimedia PC, WWW browser, and an Internet connection to use MANIC without having to download any MANIC-specific software. In retrospect, this decision to leverage existing client-side software and focus our development efforts at the server side was a good one.

There are two optional pieces to the architecture. The first is the student model server, which keeps track of activities of individual students and constructs a model of the student's behavior. This model can be used to customize the course material to tailor it to individual student's need (done on-the-fly). The second optional component of MANIC software is the proxy. As shown in Figure 1, the proxy is neither at the client nor at the server. This piece of the software is primarily used to reduce the response time (download time) of client requests. The proxy is advised by the student model server on the documents a particular student is likely to see next. The proxy prefetches this document from the web server and stores it on a local disk. If the "guess" made by the student model server is accurate, the download time for the document will be negligible, as the proxy will be able to serve the document from its local cache [Padmanabhan & Mogul 96].

3 Features of the MANIC Environment

In this section we describe the user's interaction with the MANIC system as well as the features of the system that enhance this interaction.

3.1 Non-linear perusal of course material

A design goal of MANIC was to allow students to have an active role in the way they see the instruction. Interactivity is important in order to keep students interested in the material [Hannafin & Sullivan 95]. To provide for interactivity, students are given the opportunity to browse the material at their own pace, stopping and starting the audio at will. However, students also have the option to view the material as they would in a traditional classroom (e.g., where synchronized audio and HTML playout continues non-stop for 60 minutes or more). Students can switch between either mode at any time; they are not restricted to only one mode of interaction. When a student begins browsing after having listened to the audio, the playback is stopped. The student must then begin the audio again explicitly if desired.

Because we want to allow students to browse the material in a non-linear fashion, we have decided to include a method in which students could jump to other parts of the course easily [Eklund 95] For this reason, we have included a table of contents which allows students to see the structure of the material as well as to jump to new material with one mouse click. We have also added an index of topics as well as a text-based topic search engine. To further allow for easy browsing, we have added "next" and "previous" buttons to each slide. These buttons link to slides immediately following and immediately preceding the current slide, in the linear ordering. In this way, students can linearly browse through the course without relying on the index.

Since students may be browsing the material, they may want to hear the audio for only one slide and no others. Therefore, we have designed two play modes: play continuously from the currently displayed slide onward, and play the audio for the current slide only. The first mode will play the audio from the current slide and continue until the user stops the sound, automatically changing the slides during the playback. The second mode will play the audio only until the end of the slide is reached.

3.2 Highlighting of course material

The earliest versions of MANIC simply displayed a static HTML page while the audio associated with that page was being played out. It soon became apparent, however, that such a static display was rather dull. To make the material more interesting and to capture/focus the student's attention, we chose to dynamically highlight selected portions of text within the single "page" of notes displayed by the browser. Now, as the audio progresses through the displayed page, the highlighting within the page changes. This helps the student to follow the material on the slides while listening to the audio.

Dynamic highlighting is achieved by downloading a different HTML document each time the highlight changes. Thus, several documents may contain the same basic text but will have different portions of the text in the highlight color (red). The repeated download of HTML documents proved to be problematic over 28.8K modems. Half of the bandwidth was occupied by the audio stream almost all the time. The remaining bandwidth proved to be too little for effective downloading of the new document each time the highlight changed. This led us to provide an option to the user whereby the material can now be viewed with or without highlighting. In general, we have decided to categorize users by bandwidth, CPU processing power, and memory available to them.

3.3 Displaying supplementary material

Simply putting the slides and audio on line without any changes is rather shortsighted. While traditional classrooms require linear delivery of material, the WWW allows for non-linear presentations. To take advantage of this, we have added the index as well as hypertext links to supplemental materials. The hypertext links present related information to the student, sometimes in the form of review material and other times in the form of interesting sidenotes.

However, when students access additional material, they should not lose the original context [Stinner 95]. Therefore, when a student clicks on a hypertext link or chooses to view the index, an additional window is spawned to present that material. With this method, students can view all the information simultaneously.

3.4 Putting user controls in HTML documents

As discussed in section 2.2, the RealAudio player is actually the controlling application on the client side. However, the RealAudio player provides a cassette-deck-like interface to audio. Some RealAudio controls, such as those that start and stop audio/HTML playout are appropriate for a stored delivery system such as MANIC. Other aspects of the RealAudio interface are not appropriate. For example, the only way to index into audio using a RealAudio player is by time (e.g., "move the playout to 35 minutes and 16 seconds into the audio"), whereas a better method for indexing into material is by content (e.g., "move forward to where the instructor begins covering a specific topic"). In addition, user commands for requesting help and sending in commentary on MANIC are also required.

Thus, we decided that user controls needed to be placed within the HTML documents (i.e., displayed and accessible in the "page" of notes being displayed in the WWW browser) rather than via the standard RealAudio control. In essence, we "hid" the RealAudio control interface from the student using our own control interface instead. Each of the control buttons in the MANIC interface activates a CGI script on the server which forces the RealAudio client and server to perform the requested operations.

3.5 User tracking and intelligent tutoring

One of the long term goals of the MANIC project is to provide the users with training material tailored to their rate of progress and other individual preferences. To achieve this goal it is essential to keep track of actions taken by individual users. The HTTP communication protocol does not support this as it is a stateless protocol. Hence single-session cookies [Gundavaram 96] were used to create a "session" out of the stateless HTTP protocol. The cookies carry information such as user login name and visual preferences and allow user-specific actions (such as logging information in proper files) to be taken.

The same mechanism allows us to distinguish between registered and unregistered users. Registered users are required to fill out a small HTML form at the beginning of each session. The form and the associated CGI script captures and sets the user id in the session cookie. If this information is not present, the user is considered to be an unregistered user. Using the information in the user id field of the cookie, it is possible to track users' progress, their access patterns etc.

4 Future Work

In this section we discuss ongoing and future work for the MANIC project. Specifically, we discuss how to make the course material more individualized for each learner.

4.1 Making the material less like a "course"

The materials used for the first course made available via MANIC were directly adapted from pre-existing in-class materials. The current delivery of the course still retains many aspects of the traditional classroom. For example, the slides are mostly black and white; the audio for the course is focused towards an "in-class" audience; the instructor does not tell the student about the hypertext links in the on-line materials. These will change as instructors gain more experience with teaching a live class while keeping an eye towards making the materials available on the WWW via MANIC.

As noted earlier, our ability to generate material being sent to a student "on the fly" opens up the possibility of customizing MANIC material for individual student needs. Thus far, the only customization of the material is the part of the slide that is being highlighted. However, a main focus of our current work is on the use of student modeling and intelligent tutoring. From an educational standpoint, it is imperative that we incorporate more intelligent tutoring properties into the current system [Bloom 84]. One way to do this is to add quizzes which students can take on the course material. The grades from these quizzes can be used to update a "student model", which is used to track a student's abilities on the topics within the course. Furthermore, given that MANIC tracks and records every action the student takes, it knows which slides have been seen, and thus which material has already been covered. With this information, the system can tutor students by suggesting material on which they should concentrate, or even alter the material the student sees based on the student model. The tutor can also provide quizzes to the student that are at the right level of challenge. With intelligent tutoring, we can tailor the presentation of the material so that it is customized towards each individual's students likes/dislikes and abilities.

4.2 Intelligent prefetching

One way to reduce delay in network transmission is to prefetch the material that will be displayed to the user. While this is not a new idea, we intend to extend the prefetching process by using intelligence derived from the student models. The system can predict (with some uncertainty) the slides the student will be viewing next, and can download those to the client before they are explicitly requested. For example, if a student is proceeding through the course in a linear fashion, the system can detect this and send the next set of slides in the ordering.

To implement the intelligent prefetching, we are using a proxy that will work between the client's browser and the server. This proxy will be able to cache course material. When a request is made from the client, if it is in the cache, then the data does not have to be downloaded from the server. The information about exactly what to cache is determined by the server. Whenever the proxy connects to the server (which it will do even when the page is served from the cache, if only to log the user's action), the server will determine from the student model, and possibly from more general population models, what should be cached. The proxy will read this information, and will then request pages to be sent to the proxy's cache – hopefully just before they are needed by the student. The server can also send information about when to remove data from the cache. If it is unlikely a student will need to see a slide that has been cached, then it should be removed.

4.3 Annotations

The ability to make annotations on the course material is an important learning tool. The annotations can be classified into three categories: personal annotations, annotations visible to a certain group and "global" annotations. Personal annotations would be made by individual students and the text of those would be visible only to the student making the annotations. Group annotations can be made by any person in a specific group and all members of that group will have access to them. Global annotations can be used by the course instructor to clarify difficult topics. Note that the annotations can use HTML syntax and include links to other slides in the course material or to outside sites (e.g. Request for Comments (RFCs) of various networking protocols). Currently we are designing an "Annotation Server" that will support such note-taking capabilities.

5 Conclusion

We have built a simple yet flexible asynchronous distance learning environment that takes advantage of the latest advances in the computation and networking technologies. This prototype learning environment has several interesting features such as user tracking which can be used to provide individualized instructions to each student. Future work includes implementation of intelligent prefetching algorithms, building of an annotation server and creating a prototype course which can be customized for individual student's needs. We are also working on incorporating video into the available on-line course materials.

Abstract Both students and teachers see multimedia as programmed learning revisisted, rather than a serious and long-term strategy for developing knowledge bases. This has partly come about because of a lack of formal motivational planning. This paper seeks to address this issue by identifying eight attributes of motivation and engagement and discussing a purpose-built program "*Principles of Financial Investment*" which has been implemented into the existing teaching program to determine whether students were motivated by a topic normally found to be dull and uninteresting. Formative evaluation studies conducted suggests that students found the program to be engaging, and would like to experience more interactive multimedia of this type.

INTRODUCTION

Of all the instructional media available to educators, it is interactive multimedia (IMM) which has most recently captured the attention of instructional designers, teachers and product developers. One of the reasons for this is that IMM seems to have the ability to reduce contact time between the instructor and class and provide education for mass audiences no matter where they are located. It is predicted that by the year 2000 computers will be utilised in some form in more than half of education and training delivery (Harrington, McElroy & Morrow, 1990). One problem facing adult users of IMM though, is that while there is a high degree of development of educational multimedia overall, the majority of the creative energy and money expended on IMM development is directed towards children's "edutainment" and ignores the special needs of adults. A comparison of IMM developed for children with that developed for adults reveals that developers of children's software go to great lengths to provide appealing and engaging interfaces and content, whereas developers of adult software often ignore this aspect. Many times the development is simply a matter of taking existing content and adding some multimedia elements.

At Edith Cowan University (ECU) in Western Australia, we are moving more and more to provide instructional settings for our students that recognise the value of student-centred learning environments over the more traditional teacher-centred approaches (eg. Herrington & Oliver, 1995). A key strategy in this move has been the development of IMM and other forms of computer-based learning materials. One factor of which we are continually aware, though, is the need to ensure that the materials developed meet the affective needs of the learners as well as the cognitive needs. Conventional teaching methods are very familiar to all the students and most are comfortable with them. The move to computer-based teaching and learning has the prospect to alter this comfort level. We have recognised the need to ensure that the materials we develop are appealing to the students and encourage and stimulate student use. This paper describes a project undertaken at ECU that is looking to explore factors and attributes of IMM environments which can attract and engage adult learners and can contribute to the learners' willingness to stay with a program to achieve its full learning potential.

FACTORS INFLUENCING MOTIVATION AND ENGAGEMENT

It is necessary to understand the way learners interact with IMM if the program is to be designed to motivate and engage. IMM has the ability to frequently effect changes as learners progress, moving from low level understanding through to a degree of expertise and each of these stages needs to take into account motivation and engagement. Our project has involved an extensive review of the literature describing instructional design, computer-based learning, andragogy and learner motivation. This review has revealed clear patterns between desired learner behaviour and motivation and a program which recognises this in its design is much more likely to be engaging and to lead to enhanced learning outcomes.

In general terms, the literature suggests that a motivating multimedia program tends to include experiential and exploratory features rather than the buttons and menus associated with productivity software. A motivating environment is also one which includes authentic activities and anchored instruction (eg. Laurel, 1991), is interactive, challenging and includes expert performance and guided discovery (eg. Hedberg & Harper, 1996). Our analysis and synthesis of the relevant literature suggests that there are a number of discrete factors that are important determinants and significant contributors to the development of engaging and motivating computer-based and IMM learning environments.

Immersion

As the word suggests, immersion is where the learner is completely absorbed both physically and psychologically in the program content and is a good indication of engagement (Laurel, 1991). In order to be truly engaging and allow immersion the program must be free of gender bias and provide an authentic context for learning realistic activities (see Norman, 1994; Wynn & Oliver, 1996).

Immersion is often evident in situations where games are being played. Playing is described as a flow activity—where total immersion takes place and self-consciousness and time disappear, and where the experience is so gratifying that people will undertake it for its own sake. Games are an activity which "...because of the way they are constructed, they help participants and spectators achieve an ordered state of mind that is highly enjoyable." (Csikszentmihalyi, 1993: p 72).

Reflection

Reflection is often neglected in learning environments but has been shown to be essential to learning as it encompasses elements of decision making and problem solving. Reflective skills can be broken into four parts and taught to students. First, the students do the activity themselves and gain the experience; second, they should think about the experience, what they learned, what they felt and assimilate their thoughts into a learning perspective; third, they take these new thoughts and insights and apply them to the task to get a better theory of it; and fourth, apply this new theory and get new feedback (von Wright, 1992). The role of experience in this framework is essential (Kolb, 1984) and multimedia is therefore an ideal vehicle for promoting both experience and reflection.

Flow

Play is an important part of learning, both formal and informal (Rieber, 1996), but currently play, fun, humour and enjoyment are words synonymous with computer games played by all ages. Play, or forms of it, could be an inherent part of the design of an IMM package, and has been found to be a powerful construct for interpreting meaningful learning (Rieber, 1996; Csikszentmihalyi, 1990). An important component of games or play is having flow activities which eliminate both boredom and anxiety. Flow activities lead to growth and discovery and are dynamic in that the challenge changes constantly and is at an optimal level, thus removing both the chance of boredom and the chance of anxiety (Csikszentmihalyi, 1993).

Collaboration

Collaboration can take several forms—student/student collaboration; teacher/student collaboration; expert/student collaboration or computer/student collaboration; and it is generally agreed that when using multimedia programs, motivation increases when students work collaboratively (Litchfield, 1993). This could be because the learners provide peer scaffolding and support, gives alternative perspectives, and provides a social element which increases the enjoyment of the learners.

Learner Control

Due to the disparate nature of learners, one teaching method does not fit all. (Jonassen, 1993) confirm this when they state "That learners think, process information, and learn differently is obvious. Those differences affect the courses they take and succeed in, the careers they choose, and even the friends they select…developing an awareness of how individuals differ will clarify the process of learning and the act of teaching for educators and designers in a substantial way."

Programs with more learner control are more motivating and engaging because the learner can construct their own path through the program, control the pace at which they work, and decide for themselves how much coaching or scaffolding they need (Orey & Nelson 1994).

Curiosity

All children are curious, but curiosity is not a trait fostered with adult learners. It is an important component of play and not only helps enjoyment of the learning process, but facilitates knowledge acquisition. As Malone (1980) states "One of the most important features of intrinsically motivating environments is the degree to which they can continue to arouse and then satisfy our curiosity" (p 5). To build curiosity in to an IMM program there should be elements of novelty, complexity, surprise and incongruity and these elements should not be in the form of increased information, but should surprise the learner's expectations and their existing knowledge (Berlyne, 1968). Berlyne (1968) also points out that there should be an optimal level of informational complexity for any given person at any given time, as if the material is too complex or too easy the learner will not find it interesting.

Fantasy

It is the fantasy component of a learning program which makes it interesting and intrinsically motivating (Malone, 1980). Fantasies need to be designed to accommodate the individual differences of age and gender, for example, most females do not enjoy "shoot em up" games. It is important to note that learning is enhanced only when the fantasy elements support and reinforce the learning goals of the activity (Parker & Lepper, 1992), and that the fantasy can be maintained while proficiency increases and learning goals change (Lepper & Malone, 1987). When designing educational materials based on a fantasy context, care must be taken to ensure that the goals of the learning materials and the fantasy itself are congruent with one another (Lepper & Malone, 1987).

Challenge

In order to be challenging, IMM programs need to have in-built goals. A well designed IMM will include a higher percentage of learning goals than performance goals. Learning goals encourage students to explore, initiate and pursue tasks, rather than be concerned with performance ability (Dweck, 1986). Studies have shown that learners who pursue learning goals will be motivated to produce more work and will make more active attempts to apply learning to solving new problems (eg. Dweck, 1986). Challenging, but attainable, learning goals will create more interest and enable students to sustain engagement with the task.

An IMM program for Adult Learners

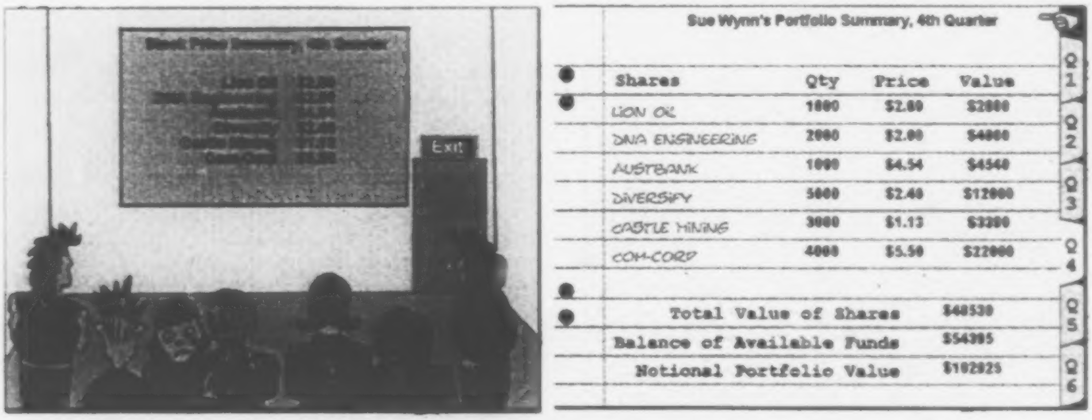
Having identified these 8 characteristics of motivation and engagement, we set about to plan a learning environment which involved each of them is some way. The learning environment which appeared to support these characteristics was a microworld. Microworlds are learning environments that simulate a small part of a real environment through which the learner can explore and discover context specific information. Papert (1980) suggests that microworlds should be simple, general, useful and syntonic—connecting new knowledge to old. We recognised that a well designed microworld should be capable of fostering motivation and engagement through these eight elements.

The learning area that was chosen to test our contentions was a course in a Business degree. A module in an introductory finance unit was targeted by the University as one where significant learning advantage could be achieved through appropriate use of IMM. This module involved teaching students about share valuation and investment. With conventional teaching learning was achieved through reading and discussion. With an IMM program, significant learning advantages seemed likely through students learning by exploration and inquiry, in their own time and at their own pace.

Principles of Finance

The IMM program that was planned to replace the conventional course was carefully designed to incorporate not only the learning sequences needed to bring about the cognitive outcomes but also to include a strong affective component.

The microworld consists of an office building called "Investment House". There is a reception area containing a help desk which can give varying degrees of hints regarding where to start and what paths to follow if the students do not enjoy browsing. Upon entering the building students are asked to register at the desk. This allows the program to be personalised and also enables them to store their data on the main computer server or hard disk if necessary. If the student tries to move on without registering a voiceover reminds them that this is a necessary step.



Sue Wynn's Portfolio Summary, 4th Quarter

Shares	Qty	Price	Value
LION OIL	1000	$2.00	$2000
DNA ENGINEERING	2000	$2.00	$4000
AUSTBANK	1000	$4.54	$4540
DIVERSIFY	5000	$2.40	$12000
CASTLE MINING	3000	$1.13	$3390
COM-CORP	4000	$5.50	$22000
Total Value of Shares			$48530
Balance of Available Funds			$54395
Notional Portfolio Value			$102925

Figure 1. Viewing room of Stock Exchange showing current quarterly share prices; and portfolio summary from the student's office desk.

There is also a blueprint of the floorplan of the building showing the other organisations within the building. These are the four main working/operating areas; the stock exchange, a stock broker, the Institute of Sound Investment and the student's office. Within these areas students can view the stock prices in a viewing room, and access their own portfolio summary from their office desk (Figure 1).

The nature of the interactions was also considered. The aim of the program was to maximise engagement and motivation, so a passive click and read type program was to be avoided at all costs. The interaction style was important as it would support the narrative intention, enhancing the participant's relationship with the product. Students should be engaged on many levels simultaneously, so it was important that the product's form, content and function should work together to create a single coherent experience communicating with the participants on a visceral level (Gould, 1995; Laurel, 1991). In this way the microworld used the principle of *form infers function* in that the design reflected the function so that the program became intuitive and the interface itself suggested to the user what it did and how it operated (Jones, 1989). Table 1 shows the 8 learner effects which we planned to incorporate and describes how each effect was built into the program.

BEST COPY AVAILABLE

Learner Effect	Program Design Characteristics
Immersion	Microworld written as though the user is the person doing the investing (first person experience). The activities are all authentic and anchored to realistic, everyday principles of investment, for example, students can observe share prices in a viewing room, visit a broker to buy and sell and view their portfolio, go to the Institute to participate in theoretical courses, visit the library, and view the portfolios of "experts". Students also have their own office and can accumulate information there for perusal at their leisure.
Reflection	The interface has been designed to simulate a stock exchange building with students able to navigate through the use of a building map on the wall of each "room". Buttons and menus has been eliminated, making the program intuitive, exploratory and experiential. Students need to think about where to go next in the program and reflect on the theory when making trading decisions.
Play	Humour has been incorporated through the use of a cartoon style interface, with humorous voiceovers when students click on certain objects or try to get into the program without registering. Gaming elements are used to involve students in the process of applying theory to making investment decisions (alea), and students compete against themselves or the expert, if they wish (agon).
Collaboration	Students collaborate with the computer to acquire theoretical knowledge and then apply that knowledge to making share transactions. Students can also get feedback from expert performance built into the program. Feedback is in the form of money earned or lost.
Learner control	The learner controls the pace of learning and order of learning and the program allows the learner to discover as much as they want. There is a built in hints and tips option for learners who want some scaffolding. The built in expert performance allows the learner to model their own investment decisions.
Curiosity	Students want to explore the program to see where they can go next. Once they start investing, they become curious to see the outcomes of their investment decisions and the impact of world events on those decisions.
Fantasy	The microworld is an intrinsic fantasy (and therefore considered more effective than an extrinsic fantasy—see Malone, 1980) in that students can imagine that they are in a share trading situation, making and losing money depending on their skill levels.
Challenge	The challenge of the program is based on meeting the goals of maximising wealth. The goals are higher order in that they demonstrate competence at the activity (Dweck, 1986).

Table 1: Learner effects and their incorporation into the IMM program

RESULTS OF FORMATIVE REVIEW

A formative evaluation was conducted with Finance lecturers and an informal review with students. The rationale for the reviews was to improve the program in any way possible, measure its effectiveness in terms of ease of navigation, and ensure that all the elements worked. The students were asked four evaluation questions based on Reeves (1996):

1. What happened?
2. How can we improve the program?
3. What learning occurred?
4. Did the program make a difference?

The five students surveyed all responded positively to the first question, enjoying the process, finding the program easy to use, and wanting to use more of this style of teaching. The students also came up with a number of ways in which the program could be improved, such as improving the flow and changing some of the conventions. These have subsequently all been implemented. All students found the concepts easy to grasp and could relate the learning to the real world, and they all found that the blend of theory and practical made the material more meaningful and more interesting.

The lecturers were asked to evaluate the program in terms of comprehension, interactivity, appeal, attitude, learning (Reeves, 1996). As a result of these evaluations more substantial changes were made, including changing the development platform to Windows95 in order to improve the usability.

Further reviews are scheduled which will be reported upon fully at the conference session.

VRML-Based 3D Topographic Maps: Enhancing Educational Applications

S. Augustine Su [1], Shueh-Cheng Hu, and Richard Furuta

WWW: http://www.csdl.tamu.edu/

Abstract: Maps are important tools in educational application. Three-dimensional topographic maps enhance understanding by providing a degree of realism unattainable in two-dimensional form. Furthermore, computer-based maps are attractive when compared to paper-based maps because they can be viewed in many different ways and because they can be stored and accessed easily. This paper presents our methodology for composing three-dimensional topographic maps in VRML, using data derived from the U.S. Geological Survey's Digital Elevation Model data. With the capability of navigation from any VRML-enabled Web browser, the maps are not only educational for map-learning primary and secondary school students, but also informative and entertaining for general users.

1. Introduction

What do maps show? For students of upper primary and secondary schools, the learning process may be enhanced by incorporating maps in a number of representations [USGS Web_b]. First, students may view an aerial-view picture of a city. This shows the region of interest but does not clearly identify the elements of that region (e.g., street names and political boundaries). Next, the students may examine a shaded relief map of the city's surroundings, including the shapes of mountains, valleys, etc. This provides a presentation of the area with moderate abstraction. Even more abstractly, students may be given a road map of the area; it may be difficult to get a good sense of the "landscape" from this map. Finally, topographic maps or terrain models, which involve many abstract notions such as contour lines, can be shown to the students.

Among these map styles, topographic maps are the most self-explaining way to make clear the correspondence of physical and man-made characteristics of locations [USGS Web_b]. However, topographic maps are printed on paper and hence present a two-dimensional encoding of our three-dimensional (3D) world limited to viewing from a fixed viewpoint from above. Consequently they do not provide an immediately intuitive representation of physical terrain.

To bridge the gap of non-intuition, we present 3D topographic maps and methodology for creating the maps in this paper. The 3D maps are encoded into the Virtual Reality Modeling Language (VRML), version 2.0 [Hartman & Wernecke 1996], and are based on "truthful data" derived from the U.S. Geological Survey's (USGS) Digital Elevation Models (DEM). The USGS is a bureau of the U.S. Department of the Interior and their models are freely available from their Web site [USGS Web_a]. With any VRML-enabled Web browser [SDSC Web] [SGI Web], users are able to freely navigate around the 3D maps, or 3D terrain, changing position and orientation of their viewpoints to observe the ups and downs of the topography.

---

[1] The author is also affiliated with Department of Computer Science, University of Maryland, College Park, Maryland

Traditional color topographic maps have only a few colors applied, so terrain is divided into a number of ranges with clear-cut boundaries. Our 3D maps are colored continuously: every elevation is associated with a distinct color, that is, colors vary when there are elevation changes. Consequently, whenever colors are appropriately selected and proper DEM data are given, the 3D maps turn out to be highly informative, showing many additional details of topography, when displayed on high-resolution, true-color computer monitors.

We also have added markers to the map to pin-point the location of major cities on the 3D maps. These markers, shown as small blue cones, are positioned using location information available from the Census Bureau's Web site [US Census Web_b], and are hypertextually linked to other sites that give relevant information.

In the following section we will show an extended example of map browsing in our implementation. We will then give detailed information about how the maps are formed.

2. Terrain Navigation

As illustration we consider a hypothetical high school geography class located in Montgomery County, Maryland, where students are studying the land forms of their region. The students have access to the Internet from personal computers in their classroom, and are examining topographical data over the Web. The teacher has introduced the color-elevation relationship and the students have linked to a Web site storing VRML-based 3D topographic maps. Under the teacher's guidance, a 3D map for the National Capital surroundings as in [Fig. 1] is brought up.

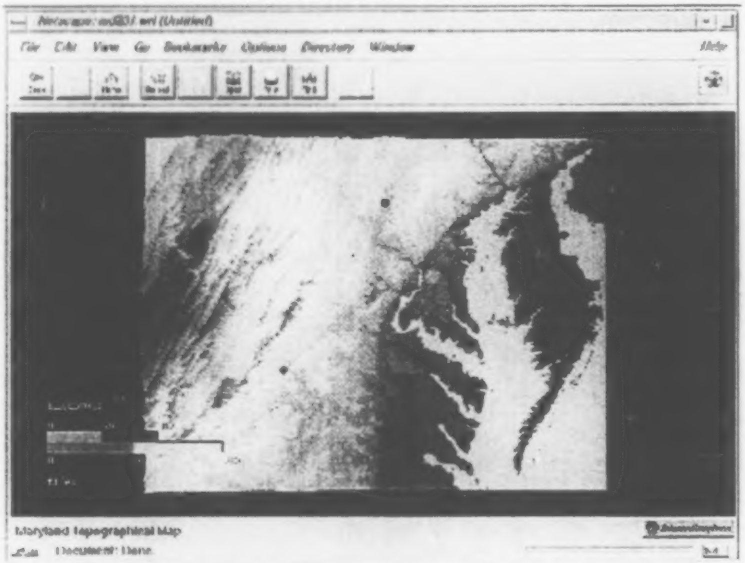

Figure 1: Areas surrounding Washington, D.C.

At first sight this is a traditional topographic map but with smooth color changes over elevation changes. However, if the map is manipulated to move the viewpoint repeatedly, things are much different. For example, viewing from the right of the map, a big bay, Chesapeake Bay, can be seen as in [Fig. 2], which is in the same map as in [Fig. 1] but from a different viewpoint.

From that viewpoint, an arc-shaped contour line looks clear, which encloses low land areas near the bay and big river channels such as the Potomac River in the center. Viewpoint changing, or navigation, is just like viewing from an airplane: Not only can the airplane fly in any direction, but also it can pitch, yaw, and roll. In addition, there are a number of indicators (blue cones on the map) to hypertextually link the locations of major cities (at the tips of cones) to city information on the Web to enhance readability of the map.

Maryland Topographical Map

Figure 2: Chesapeake Bay

The airplane can fly further towards the west crossing plains and entering the first mountains en route. This is the Blue Ridge Mountains. A new viewpoint appears as in [Fig. 3]: with the Blue Ridge on the right, the Shenandoah Valley in the center, and the Appalachian Mountains on the left. From the map the teacher can explain to the students the reason for the beautiful scenery of Skyline Drive (built on the ridge of Blue Ridge Mountains), where they had a field trip earlier. Furthermore, since the valley looks very flat here, the construction of Interstate Highway 81 can be justified.

3. Issues of Map Making

3.1 Resources on the Web

The basis for our map making is the extraction of elevation data from DEM data, which are available from USGS Geo Data Web site [USGS Web_a]. The DEM data that we used are called 1-degree DEMs, where each file of a DEM is in plain text with latitude and longitude information plus 1,200 x 1,200 elevation data points for each 1-degree-by-1-degree block within the whole continental United States. In other words, one elevation data point is given (in terms of an integer in unit of meters) for every 3 arc second along a meridian (which is 93 meters or 300 feet [Pearson 1990]) by 3 arc second along a parallel (which is 300 feet times the cosine of the latitude at that point). The size of a gzip-compressed DEM file mostly ranges from 0.5 MB to 1.5 MB.

BEST COPY AVAILABLE

The data with a resolution of 1 arc second (30 meters or 100 feet) by 1 arc second also are available from the USGS if more detailed data are needed. The size of this DEM is about 9 times that of a 1-degree DEM. Since we do not plan to compose 3D maps of such detail, the 1-degree DEM is enough to serve our purpose in consideration of storage efficiency.

Another useful resource is the U.S. Census Bureau's Gazetteer [US Census Web_a], which provides census data for all U.S. cities including their latitudes and longitudes. Based on the information, small blue cones were displayed in the current implementation to pin-point city locations.

3.2 Contour Lines Coloring

There are many ways of color drawing in 3D maps. In the current implementation, each elevation is associated with a different color. More specifically, eight major colors are picked to associate with eight pre-selected elevations (See [Tab. 1]). Then, any non-pre-selected elevation is associated with a color linearly interpolated in RGB space between two major colors such that the elevation is between the associated elevations of those two colors. Based on this color scheme, nearby elevations have similar colors. Our color scheme reflects more change in lower elevations than that in higher elevations since in general more locations are at lower elevations than at higher elevations.

Meters	**Feet**	**Red**	**Green**	**Blue**	**Color**
8000	26247	1	1	1	white
2500	8202	0.1	0	0	dark wood
1500	4921	0.5	0	0	wood
1000	3281	1	0	0	red
500	1640	1	0.5	0	orange
250	820	1	1	0	yellow
100	328	0	1	0	green

3.3 Map Projection in VRML

Since the data of each DEM are uniformly distributed in a square grid under the latitude and longitude coordinate system, it is natural to pick the ElevationGrid node in VRML as building blocks for 3D maps. That is, our map projection is a kind of Mercator projection [Pearson 1990]. Under this projection, the distance relationship is preserved in meridians; the length of a degree in a parallel is proportional to the cosine of the latitude at that point. Unfortunately the ElevationGrid node is a rectangular grid without the above attributes. For a map covering a large area, the latitude difference between the top and the bottom of the map are small and can be ignored. For a map covering a small area, the latitude difference is relatively large and should be considered.

For simplicity, a parallel near the center of a map was picked to approximate the scale of all parallels in the map. That is, in 3D maps the ratio of the length of 1 degree in any parallel to that of 1 degree in any meridian is fixed, which is the cosine of the latitude of the central parallel.

3.4 Elevation Exaggeration

Except for steep mountains and valleys, the 3D topographic maps with truthful elevation data are usually very flat and not distinctive if the vertical and horizontal distances are at the same scale. For this reason, map elevations are commonly exaggerated to draw attention to changes in the 3D terrain. This rule applies to our 3D maps, too.

3.5 Boundary Lines Cutting

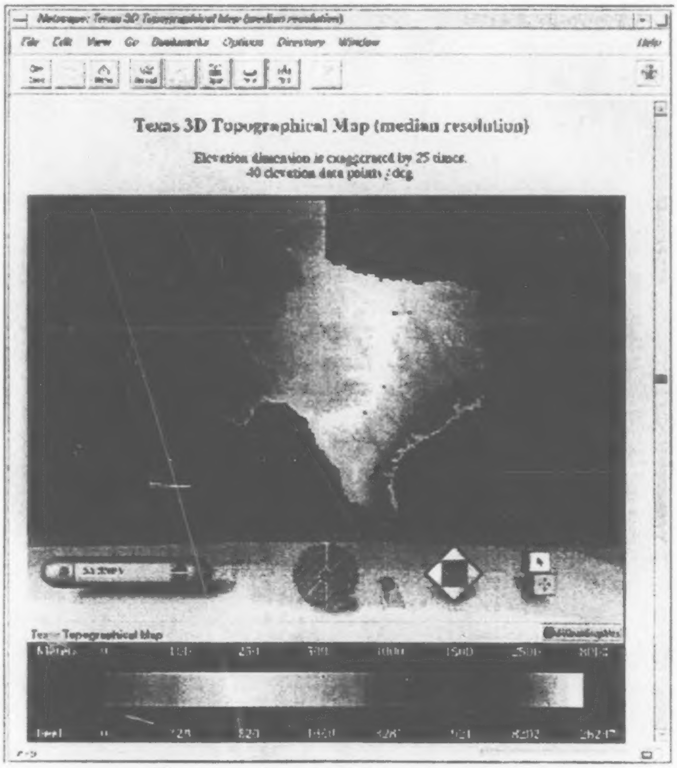
Since the DEMs are always in 1-degree-by-1-degree blocks, there is no boundary information such as state or county lines carried in the DEMs. Digital Line Graphs (DLG) from the USGS Geo Data Web site [USGS Web_a] can serve this purpose. However, due to the limited time available for this implementation and the fact that the DLG data were digitized from physical maps, we selected to "digitize" the borderlines we needed from a printed map with pencil and paper. Every ElevationGrid node involved with borderlines has been replaced with a group of smaller ElevationGrid nodes that approximate the lines. This is a divide-and-conquer approach.

3.6 Elevation of Zero

Since the DEMs do not distinguish the water bodies from the land, we cannot tell the ocean from the coast because elevations below 0.5 meter are rounded to zero in the DEMs. In the current implementation, the elevation of zero is treated as the ocean and is colored in blue. Therefore, some low lands are inevitably "washed out" in our maps. Accurate coastal lines are required to offset this problem.

4. Implementation

Two state maps were composed to prove the concept of methodology: Maryland without border trimming (see [Fig. 1]), and Texas with border trimming (see [Fig. 4]). Also, two assistant scales were included: a color bar chart for land elevation and a mileage scale. There were 15 DEMs in total employed for the Maryland maps; 82 for the Texas maps (among them, 33 involved with the trimming process where each was split into ten long strips to approximate the Texas state line that was manually delineated from a physical map [USGS 1967]). All of the maps are exaggerated in the elevation dimension by about 20 times.



Texas 3D Topographical Map (median resolution)

Elevation dimension is exaggerated by 25 times.
40 elevation data points / deg

Figure 4: Texas 3D Topographic Map

BEST COPY AVAILABLE

For the issue of map projection, the 31-degree parallel, which is about equally distant from Houston and Dallas, was picked as the central parallel for the Texas maps (the ratio is 0.857); the 38.5-degree parallel was chosen for Maryland (the ratio is 0.7826).

With a resolution of 1,200 data points per degree, the 1-degree DEMs afford enough details for almost all small and large scales of US topographic maps. However, considering the resolutions of computer monitors and various processing powers of machines, we decided to deliver maps with 3 kinds of resolutions: a low resolution at 10 x 10 points per 1-degree-by-1-degree block, a median at 40 x 40 points, and a high resolution at 200 x 200 points. All data sets were uniformly sampled from the DEM data.

Since the location of a city in the maps is 3D, three coordinates are needed. Besides the latitude and longitude information from the Census Bureau, the elevation coordinate is selected to be the elevation of the most adjacent point in the DEM data. Then, the three coordinates are transformed into a proper VRML coordinate system to pin-point a city.

Some efforts were made to shrink the sizes of VRML files to reduce downloading time, such as dropping unnecessary zeros before decimal points, deleting unnecessary spaces, limiting RGB values to two-digit decimals (since human eyes may not be able to tell more than that), and finally compressing VRML files.

5. Future Work and Conclusion

Currently our 3D maps do not deliver information about rivers, lakes, highways, and land use, which can be built in the future based on USGS DLG data. We are considering incorporating user-specified modifications to the color scheme and the overlaying of satellite images or weather information for visualization purposes. In VRML 2.0, sensor nodes can send out events containing the 3D coordinates of points clicked by the mouse. This provides the basis for carrying out a 3D counterpart of the clickable imagemap on the Web. Based on this idea, a 3D topographic mapping service similar to Census Bureau's TIGER Mapping Service [US Census Web_a] can be accomplished in the future.

Our 3D map implementation can be viewed on the Web at http://www.csdl.tamu.edu/topomaps/.

Intelligent Agents for Teaching People How To Cooperate

Kathleen M. Swigger, Robert Brazile, Dongil Shin, Letatia Ducksworth
Department of Computer Sciences
University of North Texas, USA

Abstract

Various systems have demonstrated the effectiveness of intelligent agents in a number of different applications. Agent technology that supports groups of users located in different geographical areas has been scarcer. Our intention is to create software that is designed to adapt to a group's needs by offering a variety of help and support when required. In order to accomplish this goal, we built a series of advisory-style agents that support group planning activities. The agents access an adaptive group model that contains information about the group's plan, activities, and expertise. AI reasoning techniques are used to match the help to the needs of the group. This help comes in the form of text and examples. Thus, the system attempts to provide instruction to groups on how to work together to improve the planning activity.

1 Research Objectives

As the information superhighway continues to grow, we are being forced to re-examine the way people work. The idea of the "office worker" is gradually being replaced by a simple connection to e-mail that makes it possible to have rapid and frequent interaction with people throughout the world [Whitaker, Frohlich & Daly-Jones 94]. Yet, in spite of this rapid growth in telecommunications, most network applications continue to favor individual rather than group work. Our intention is to fill this gap by creating a series of applications that contain advisory-style agents that can facilitate groups of people working together over a distributed network. The specific context for this work is programmers engaged in planning a large programming project. The advisory agents are able to detect ineffective collaboration and provide groups with information about how to improve their activities. Furthermore, the agents can initiate communication, monitor events, perform tasks, and aid in collaboration with other workers. The metaphor for such a system is a coach who encourages his/her players to work together as a team. Our vision is to create a "coaching" system that provides a method of mentoring groups through electronic means.

2 Related Literature

Much has been accomplished already in demonstrating the potential of using agent software in combination with various network software products for communicating and seeking information [Barron et. al. 94] [Maes 94]. For example, there are systems that incorporate information from different sources [Gruber 91]; ones that search for loosely specified articles from a range of document repositories [Voorhees 94]; And, still others that allow heterogeneous database systems to work together to answer queries [Hughs el. al.]. Missing, however, is the development of agent software that exhibits clear advantages to working over the network as a member of a team. While we know that network technology can be used to empower individuals with the latest information, we also know that it lacks the in-depth contact among small groups of workers that is at the heart of every corporation [Whitaker, Frohlich & Daly-Jones 94]. Thus, our prototypes and models must clearly demonstrate how network technology can evolve into an ecosystem of information, communication, and innovative mentoring that supports not only individuals but groups of people working together.

In order to address this problem, the authors engaged in a number of innovative group software projects sponsored by various funding agencies over the past several years [Swigger, Brazile & Shin 95] [Swigger & Brazile 95]. In order to enhance a group's understanding of various activities (e.g. library database searching, requirements elicitation, and cost center analysis), the authors built several computer-supported cooperative interfaces that facilitate cooperation. Groups learn to become more effective collaborators by using specially designed computer tools that enable them to organize and systematize their interactions. The cooperative interfaces rely on a shared window system (i.e., What you see is what I see) that allows groups who are geographically distanced from one another to execute controlled tools in shared windows. The systems have been implemented using C++ on a number of different platforms, all connected to a local area network. The interfaces themselves consist of a series of online tools designed to support specific group competencies deemed important to effective group communication. Results from studies that compared groups who used the experimental cooperative environments versus those who performed the same tasks face-to-face indicate that the systems are able to improve task performance [Swigger & Brazile 95]. This interaction was significant when a t-test was computed on these data ($F=5.66; p < .001$). More importantly, the software has been recently transferred to several real-world environments and is currently being used by companies involved in another NSF project investigating team effectiveness.

While the above groupware seems effective in supporting collaborative work, it lacks the coaching capabilities that enable participants to *improve* their collaborative skills. After much discussion, it was determined that a set of advisory style agents might help groups with their initial planning tasks as well as assist them in resolving conflicts that occur as a project progresses. In order to meet this need, we built a series of coaching agents that support these two functions. The agents are designed to detect ineffective collaboration among groups and provide them with information on how to improve their activities. A second series of agents help monitor the work flow and help negotiate new planning tasks. A more long-term goal of the project, however, is to develop a new metaphor for working; one that embraces the idea of collaboration. We would like to move users from their specialized environments into a shared, multi-user setting where diverse groups within an organization can collectively solve problems.

3 The System Overview

Using the techniques developed in the previous research, we built a special interface that encourages participants to cooperate more effectively. The specific context for this application is ‘project planning,’ specifically project planning as it relates to the software design process. The idea is to create a collaborative system that helps groups of programmers with various planning tasks associated with the software design process. The specific coaching agents embedded within the application are designed to help programmers do the initial planning as well as resolve conflicts that occur after the plan has been created.

The collaborative planning software is highly interactive, allowing groups to access the interface and plan and schedule tasks. Moreover, the system supports users who are located in different geographical areas, but who need access to the same planning information *at the same time*. Users are free to use the interface to organize their planning tasks in an effective way. A typical sequence of planning tasks includes: entering the goals for the project; entering the individual tasks required for project completion; voting on tasks priorities; assigning individual members of the team to each task; monitoring the tasks after the project begins, etc. For each activity there are a set of coaching agents that help groups manage and organize that specific activities. For example, the ‘agenda’ task includes a set of agents that help set and manage conflicts among agenda items. Similarly, the scheduling task is supported by an agent that resolves scheduling conflicts.

3.1 The System Components

The specific components of the system include: a) A special collaborative planning interface, b) The “agent” software designed to help groups with planning activities, and c) The support programs that manage the communications and database functions. The special planning interface was developed using Groupkit, an applications development package designed by researchers at the University of Calgary [Roseman & Greensberg 96]. Groupkit is a series of software modules that help developers create and integrate special purpose tools that support collaborative activities such as brainstorming, white boards, group management systems, etc. Although the interface was generated with the help of Groupkit, the specific system is designed as a client/server architecture whereby items are stored in a database on the server and may be viewed independently by the various members of the group. Client processes interact with users, gather information, and request the server whenever they need to access the shared database that records the information on groups, members, and agenda items. The server process manages the object-oriented database and interacts with the client processes through a Groupkit environment. [Fig. 1] shows the overall architecture of the shared data access and the database management system.

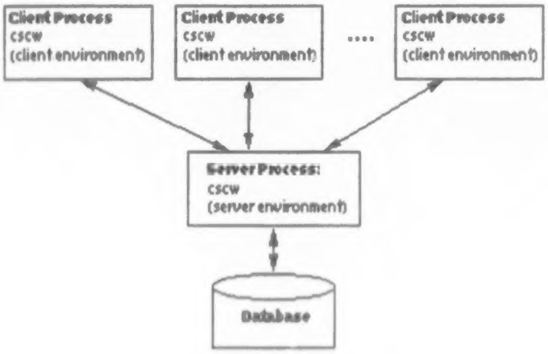

Figure 1: Client/Server Environments for Shared Data Access

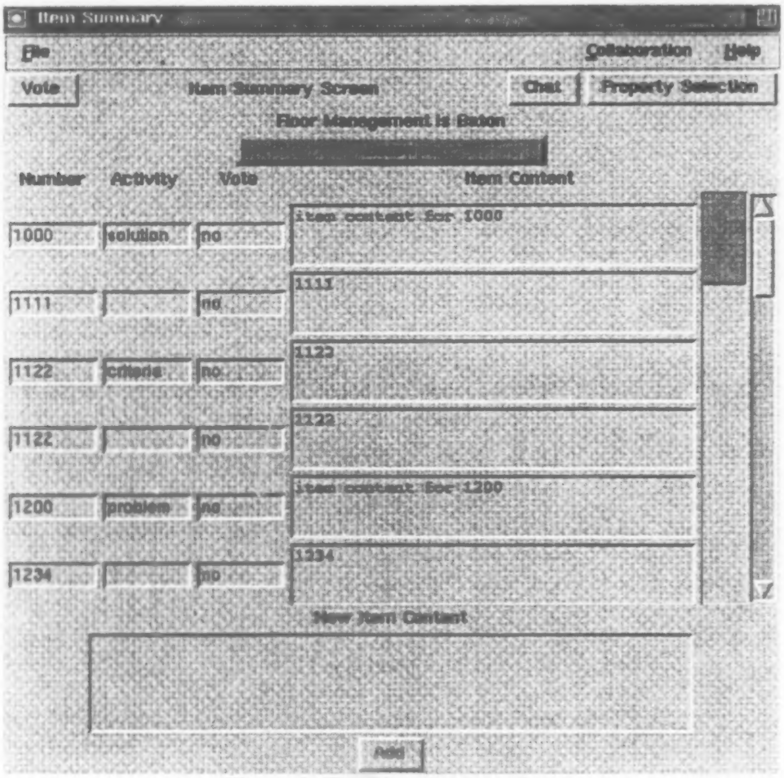
3.2 The Collaborative Planning Software

The planning interface consists of various columns and rows that can be configured according to the user's needs. The users can alter the interface by simply changing or adjusting various properties. The interface itself allows users to enter items, give priority to items, vote on items, sort items, and identify the author of item, date it was created, etc. (see [Fig. 2]). There is no fixed way the groups interact with the software. Rather, groups are free to select among several different types of floor management styles including: 1) Director (i.e., a single person selects who and when members interact with the system); 2) Baton passing (i.e., the person who currently controls the system selects the next person to interact with the system), and 3) All-at-once (i.e., everyone is free to interact with the system at any time). Based upon which floor management style is selected, members can enter, view, and change any information on the screen.

All information entered on the screen is then stored in the system as an item or a part of item. As a result, items can be deleted, re-sequenced, displayed, etc. Other attributes associated with items include time and date created, author, priority, and type of activity. The latter attribute is assigned by the system and is used by the agent intervention software to make decisions about when to interact with the users (see below). Each member's transactions are also stored in the database and used by the agent intervention software. A more detailed explanation of the agent software now follows.

3.3 The Coaching Agents

As previously mentioned, the special planning software has the "instructional" goal of assisting groups with collaborative skills. The system accomplishes this goal by invoking a series of coaching agents that intervene and offer advice whenever they detect ineffective collaboration. In our previous research, we found that groups can improve their group's performance if they use effective collaborative skills. The skills found to be most predictive of effective cooperative problem solving include those that support problem orientation, help establish criteria, assist in establishing correct operating procedures, help generate alternative solutions, and facilitate the evaluation of the solution [Swigger, Brazile & Shin 95]. We believe that these same cooperative skills can be to help groups plan more effectively. Thus, each of the items in our interface (see above) has been assigned an activity attribute that corresponds to one of the skills that leads to more effective group performance. For example, whenever a group changes an item, the system records an activity attribute that indicates that the fourth skill (i.e., generation of alternative solutions) is being exercised. Similarly, whenever the group votes on an item, the system records that the skill of "evaluating the solution" has been performed.



Number	Activity	Vote	Item Content
1000	solution	no	item content for 1000
1111		no	1111
1122	criteria	no	1122
1122		no	1222
1200	problem	no	item content for 1200
1234		no	1234

Figure 2: The Planning Interface

The system's coaching agents have been grouped as either those that run on the server and monitor activities related to the entire group (i.e., Group Agents), or those that run on the client and monitor individual actions (i.e., Member Agents). For example, Group Agents determine whether an item has been voted on, an item has been changed and updated, or an issue decided, etc. On the other hand, Member Agents watch whether a particular member of the group has participated in the discussion or made a statement, etc. All the activities of the Group Agents are handled through a Master Event Handler that is responsible for placing the requests on a queue, activating those requests, and re-directing information. Member Agent activities are handled in the client workspace, but can be sent to the Master Event Handler for additional processing.

Individual agents are then created by defining 1) a set of statistics that can be used to determine intervention (in the form of an SQL request to the database), 2) the event(s) that will trigger the intervention (in the form of a rule), 3) the specific content of the intervention message, and 4) the location(s) of the intervention message. Thus, each agent can be designed to look for evidence of good and poor behaviors, and then coach group members to become more effective in a particular area. Since all the information is stored in the database, the coaching agents can ask for specific data that allow them to recognize a sequence of effective and ineffective behaviors. Because the items are associated with a particular competency, the coaching agents can intervene whenever the group is demonstrating ineffective behavior (see [Fig. 3]).

Figure 3: The Voting Agent

4 Current and Future Directions

We are currently evaluating the effectiveness of the system. The major questions that we wish to ask are: To what extent are the advisory agents effective? What are the benefits of using the advisory agents over other techniques? These questions will be answered by examining the data recorded by the coaching system and comparing it with groups who do not use the software. For example, output from groups using the coaching agent software will be compared to the output from groups who engage in these planning activities without the advise. We believe that those groups who use the cooperative environment will have significantly more user satisfaction and higher "performance" than student groups who do the same task face-to-face.

We are also constructing a second model of group intervention that concentrates on the runtime portion of the planner. Once a project is underway, it is important for groups to be able to modify plans and engage in iterative processes that involve the generation and refinement of ideas and solutions. A coaching agent that can detect problems in the plan, notify members of potential problems, and encourage groups to pursue different alternatives should facilitate this particular competency.

Since a group identifies group/task relationships while creating an initial plan, coaching agents can be built that use previous information to notify specific members about potential conflicts that might occur after the project has started. Potential conflicts can occur if a member fails to complete a scheduled task, an objective changes or is altered, or a task is no longer valid. The system will "advise" specific members or the entire group to re-visit their objectives to determine whether modifications should be made. Since our previous research has indicated that group effectiveness is related to an ability to generate alternatives, we intend to design special cooperative tools that help facilitate the re-planning task. Again, special evaluation tools will be available to the participant for re-scheduling tasks as well as resolving conflicts.

5 Conclusions and Impact of Research

In conclusion, we believe that we have identified a situation for which there is a definite need for computer assistance: *A system that will teach groups how to work together*. We then described a plan for providing such a system. We explained how we have developed a prototype interface that allows us to track activities of groups using the collaborative software. We also described how we have designed a series of coaching agents that intervene whenever they detect ineffective collaborative behaviors.

In previous research, the authors found that it was possible to design an interface that could facilitate cooperation among groups [Swigger, Brazile & Shin 95] [Swigger & Brazile 95]. They also observed that it is possible to assess group performance by evaluating effective group skills through the use of particular competencies or skills. Thus, our goal is to use these results for developing broad-based systems that can be used in designing different types of collaborative software. It has been our observation that the need for cooperative skills occurs frequently in this technological society. Yet rarely do we help people develop these skills. As such, this research should provide insight and software tools to achieve this goal. Moreover, it will provide a rich environment that will allow us to investigate various issues related to helping people work together.

ELECTRONIC AUDIO-GRAPHIC TUTORIALS: A TEACHER'S PERSPECTIVE

Pete Thomas
Department of Computing, Open University, UK
p.g.thomas@open.ac.uk

Abstract: In its development of systems that exploit the Internet to support distance education, the Open University recently presented its first audio-graphic tutorial to a group of geographically remote students. This paper describes the benefits of audio-graphic tuition when compared with the more common use of electronic computer conferencing from the perspective of the teacher, and reports on the effectiveness of this mechanism for teaching. The paper also describes strategies and tactics that were found to be useful for teaching in this medium.

Introduction

This paper reports on the latest in a series of trials aimed at determining how electronic teaching can be used to replace or supplement conventional (face-to-face) teaching sessions (tutorials) [Thomas et al. 1996]. Our approach is to compare and contrast conventional teaching systems with Internet teaching through a series of large scale controlled experiments. Because this is a new field of activity, not only do we have to perform controlled experiments but also we have to develop teaching techniques which exploit the new technologies. In this paper we examine the advantages and disadvantages of using audio and graphic communication over other forms of electronic teaching such as computer mediated conferencing. Of particular interest is how well the technology enables us to reach out to geographically remote students to support their learning when distance prevents them from taking advantage of conventional face-to-face sessions. We are also concerned to provide technological solutions which are low cost in order that the techniques that we develop can be applied to distance teaching on a large scale (thousands of students on each of hundreds of courses).

Experience of electronic tuition at the Open University

A major problem that a distance education institution faces is how to reach out to students in geographically remote areas. In addition to high quality teaching materials (a combination of printed materials, video and audio cassettes, TV and radio transmissions, and computer software), the Open University also provides tutorial and counselling support to its students. Each student is allocated to an academic teacher (known as a tutor) who typically provides a small number of face-to-face teaching sessions (tutorials: similar to conventional seminars) and offers help on an individual basis via the telephone. This system works well in high population density urban areas where it is economic to hold tutorials. However, for remote students, travelling long distances at inconvenient times to a tutorial can be a significant barrier to learning; see also [Jones 1996]. It is clear that electronic communication with students in their home using the Internet has the potential to bridge the distance gap for remote students.

In 1995, a trial was held using the Internet to teach approximately 30 students resident outside the UK who were studying an introductory course in computing [Price & Petre 1996]. The Internet was used for tutor-student communications and included electronic submission of tutor marked assignments and answering student queries. The trial was sufficiently successful for it to be extended in 1996 to two courses with approximately 250 students and 25 tutors. This time, the majority of students were UK based but included students from Continental Western Europe, USA, Malaysia, and New Zealand. The success of the 1996 trials [Carswell 1996] have encouraged us to increase further the scale of tutorial provision in 1997 to over 500 students on 5 courses (not all of which are computing courses. Our objective is to improve and enhance the system in readiness for a new computing course to be presented in 1998 for which all of its projected four thousand students will be tutored electronically.

In our 1996 trials, we investigated primarily asynchronous electronic tutorials in which a conferencing system was used to support tutor-student, student-student and tutor-tutor interaction. A typical tutorial began with the tutor posing a problem and asking students to respond by posting their views on the conference. The tutor's role was to encourage all students to think about the problem and to react to other students' postings. In this way, over a short period of time (typically a week), a consensus of opinion about the problem and its solution was developed. (This is only one of several models pioneered in the 1996 trials). The advantages of asynchronous working [Steeples et al. 1996] are:

(i) low connect time (students typically use slow modems which, for synchronous tutorials, can incur high telephone charges);

(ii) more time for reflection (performed off-line) resulting in better responses to questions;

(iii) allows for time differences across the world;

(iv) enables students to participate at times of their own choosing to fit in with their personal life-styles.

Although asynchronous communication is an enabling technology, pedagogically it has the serious disadvantage that responses to student queries are not immediate as would be the case with synchronous tutorials. For this reason we investigated alternative technologies to see how they could improve the students' learning experience. For example, compressed video [Miller 1996] is extremely attractive but is extremely expensive and not at all suited to mass distance education. Interactive Remote Instruction using high speed networks and high performance workstations [Maly et al. 1996] are also very expensive and are more suited to remote classroom use. Nevertheless, some of the experiences in using these systems for distance education are applicable in our context. We required a low cost technology that could be easily set-up by students in their own homes and which could be managed easily by the tutor (also working at home). A useful summary of related work can be found in [Watabe et al. 1995] where collaborative work over the Internet is discussed.

Audio-graphic tutorials

In the Open University teaching system the tutorial plays an extremely important role:

- to overcome the isolation of the long-distance learner;
- to encourage the exchange of ideas and learning experiences;
- to enhance the delivery of distance learning materials in a structured and supportive environment.

Therefore, any electronic tutorial must meet the same general objectives, although it is clear that the student experience will be quite different depending on the delivery medium used. It is also important to note that the tutorials in this model consist of essentially small to medium sized groups (maximum 25 students, but in practise about half this number attend).

Synchronous computer conferences are well established and can be fruitfully exploited for tutorial purposes. However, the low bandwidth of keyboard communication can make synchronous tutorials rather tedious resulting in low amounts of information exchange particularly when compared to a face-to-face tutorial. The use of audio and graphical channels improves the communication bandwidth significantly.

Therefore, we have developed an audio-graphic tutorial in which the tutor communicates with a group of students over the Internet using a voice channel and a graphics interface (a whiteboard). With this technology the tutor is able to send graphical information with synchronised voice communication in such a way that students can see the graphics on their own computer screen and hear a simultaneous commentary from the tutor. In turn, the students can communicate with the tutor and other students in the group. In the trial reported on here, students

1060

were restricted to communicating via their keyboards. Although the audio channel could have been used by students for transmission, we wanted to concentrate on the educational aspects of the system and therefore reduced the number of possible problems that could arise with simultaneous broadcasts from all students in the group.

There are several approaches to the effective exploitation of audio-graphics:

(a) A lecture-style presentation, in which the tutor presents information to remote students in the form of a commentary over textual and graphical information. If performed live, this is a pedagogically inferior mechanism to traditional TV transmission or video. Its advantages lie in the fact that the tutor can react quickly to student queries by "broadcasting" answers relatively soon after the queries have been received. That is, students submit questions in advance and the tutor prepares responses prior to the broadcast. The responses could be prepared "off-line" and be stored for transmission at the allotted time. However, the fact that the medium permits the real-time construction of graphical and textual information combined with an audio commentary on what is happening is an important step forward over an asynchronous computer conference.

(b) A tutorial-style presentation, in which the student can react immediately to the material being presented. Immediate feedback to the tutor is the essential feature of this mode of working. Students can ask questions about the material to obtain immediate clarification. Thus, there is real-time interaction between tutor and students.

(c) A group activity, in which all members of the group interact in real time to solve a problem and where the tutor's role is to help, encourage and focus the activities of the group.

The Trial

The trial consisted of a group of students and a single tutor. The students were located in their own homes using conventional medium sized PCs. The tutor was located in the Audio Visual Department at the Open University where devices such as video cameras were available for recording the session. The students were volunteers currently studying a third level computing course which had been presented electronically throughout the 1996 academic year. Therefore, all participants were geographically remote from each other but had been in contact using e-mail throughout the course. The tutor was an experienced distance education tutor who had been teaching on the electronic course. The audio-graphic tutorial was the last tutorial of the course and immediately preceded the end of course examination. In the following description, only the tutorial aspects of the trial will be discussed; ensuring that the students were able to set-up and use the software is not covered here, although this proved not to be a problem.

In our trial we used WhitePine's Enhanced Cu-SeeMe (V2.0.1) for the graphics (the whiteboard) and Progressive Networks' RealAudio (V2.0) for the voice channel running over the Internet.

Arrangements for the audio-graphic tutorial began well before the actual date of the transmission (5th October 1996). The first task was to e-mail the students to say, in brief, what was going to happen in the tutorial by giving a brief summary of the mechanism and the date and time it was to take place.

About ten days prior to the tutorial, a follow-up e-mail was sent which described precisely what was going to be covered in the tutorial, that is, a past exam question would be worked through for revision purposes. Students were sent the exam question to read and asked to respond (by e-mail) requesting specific topics to be discussed in the tutorial. The information returned by students enabled the tutor to focus attention on certain aspects of the question and prepare, in advance, computer files of information that could be readily placed on the whiteboard during the tutorial.
Shortly before the specified start time of the tutorial, both sound and vision were transmitted to inform students that they had connected through successfully. This was a simple "welcome screen" together with voice-over.

The first part of the session proper was devoted to "social interaction". That is, a video picture of the tutor was transmitted (this was the first time that many of the students would have had sight of the tutor). It has been found in previous trials that an initial socialising period helps the group settle down, and ensures that attention focuses on the task in hand without becoming too concerned about the technology. This period enabled students to send welcome messages to each other as they logged on.

The tutor spent the next part of the formal activities talking about what the session was about and how the students were expected to interact. The main teaching began with a reading of the exam question, and the tutor answering the first part. This was a fairly simple step, covered reasonably quickly so that students could settle in and begin thinking about the question. The technique for interaction consisted of the tutor taking short pauses from the dialogue and giving the students direct and explicit instruction to type in any comments or queries they may have on the material dealt with so far. Most of the time the instructions were given both textually and verbally to ensure that students fully understood what was expected of them.

Having obtained a student response (e.g. the answer to a part of the question, or the next step in an argument) the tutor commented upon it. For most of the time, student responses were generally correct and the tutor simply posted the answer on the whiteboard as a record of the interaction thus far. When a response was incorrect or inappropriate it gave the tutor an opportunity for comment.

A significant issue arose: it was often the case that it was the "better" students who responded first so that not only were the responses correct, it meant that some students did not bother to respond. This situation is not unknown in the classroom, and it is up to the tutor to control the situation to enable all students to participate. More work needs to be done in this area to develop techniques and tactics suited to audio-graphic tutorials.

The tutorial lasted for approximately an hour and a half, and was concluded with the tutor summarising what had happened, thanking the students for taking part and reminding them to provide immediate feedback to the evaluation team via a questionnaire that had been sent by e-mail just before the tutorial.

Evaluation

In order to evaluate the trial the following records were kept:

- a video recording of the tutor's activities
- a video recording of the tutor's screen
- a video recording of a student's screen (we set up a video camera in a student's home)
- an audio record of the trial
- documents relating to the pre-trial set-up
- responses to a student questionnaire (given immediately after the session)
- a tutor de-briefing
- a technical de-briefing
- debriefing interviews with students

At the time of writing, all of our data records had not been analysed in full, but the initial feedback from students was extremely favourable. They had enjoyed the experience, the audio and graphical reception was generally good (although there was one breakdown in communications during the tutorial), but more importantly they admitted to a positive learning experience. Somewhat unexpectedly, students reported a sense of belonging to a group, something they had not previously experienced.

With the current state of the technology, working over slow modems (14.4bps), the sound quality provided by RealAudio was much superior to that of Cu-SeeMe. However, the whiteboard and chat window (the mechanism by which students corresponded with the tutor and other students) worked well. The major problem with the set up was the delay in the tutor's output being received by students. Student responses were received by the tutor almost instantaneously, but the tutor's comments took up to 30 seconds to be received by the student. At times when the tutor was talking and drawing on the whiteboard all was well. However, when the tutor asked for student responses, not only did allowance have to be made for "thinking time", the electronic delay also had to be taken into account. In a situation in which there are no other signals emanating from students, it is difficult to know what the tutor should do: simply doing nothing does not seem to be an option. A communications line with no activity on it can appear not to be working and this causes the participants to worry over whether or not the technology is faulty instead of concentrating on the tutorial activity.

From the tutor's perspective, the following lessons were learned and will be useful in future tutorials:

- The tutor should not leave long pauses in audio output but should continue the dialogue in order to confirm that the tutorial is still "live" and there has not been a breakdown in communication. If a pause is required, the tutor should say so explicitly.
- The tutor should ask for frequent responses from students and not simply turn the tutorial into a lecture.
- As far as possible, ask questions which elicit brief answers (students and tutor alike cannot type quickly enough for anything else to be an effective use of the available time).
- The tutor should wait for a sufficiently long period of time for students to respond to questions. This is irrespective of whether or not there is any delay in the communications medium because there is no immediate visual or audio feedback from students to indicate that they have understood the question and, if so, whether or not they intend to offer a solution. The tutor just has to wait until at least one typed response is received. Rather than simply wait quietly, the tutor can repeat the question and give suggestions as to how the students might usefully go about providing an answer.
- Use techniques employed in TV presentations such as (a) slow movement of pointing devices and (b) synchronise the pointer with speech, that is, do not point at one thing and talk about something else.
- Remember that this may be the first time students have heard the subject matter being spoken. The actual pronunciation of technical terms (jargon) may throw the student.
- Keep the voice and content fairly "light-hearted" to maintain interest.
- Repeat the important parts of the commentary to overcome problems of poor audio transmission and breaks in concentration of the student.
- Recognise that the electronic system will fail (to some degree) and will inevitably detract from the tutorial.
- Remind students to take "notes" from time to time by taking a file copy of the contents of their whiteboard.
- Use both audio and visual mechanisms to convey instructions to the student.
- Be disciplined in the use of time, particularly in allowing student responses.
- Have well prepared files available for the major parts of the activity. Good preparation can avoid a lot of wasted "air-time".

Discussion

The tutorial was deliberately based on the investigation of a problem in computing that involved:

- analysing a piece of text;
- building up a diagram (of a binary search tree);
- using mathematical expressions.

Thus, the dynamic properties of the medium were exploited in the following ways:

- Students could observe how binary search trees were built up and hence deduce their properties.
- Students could provide expressions as part of a mathematical demonstration. Mathematics, if used wisely, can be a powerful technique in this medium because it can be the case that the solution to a non-trivial question can be stated quite succinctly.
- Various parts of a diagram or mathematical expression could be pointed to whilst being described.
- Cutting and pasting so that parts of a solution could be visually compared.
- Reading a question.

On the negative side, there is a great temptation for the tutor to take over the tutorial completely and fail to let the students interact. This seems to be due primarily to the remoteness of the participants. Without the visual and audio "clues" that one finds in a classroom (or that can be found in video communication) there is little feedback that can help the tutor decide how the tutorial is progressing from the students' point of view. Continual checking of the students well-being by asking questions seems to be one device that can be used.

Summary

The trial has shown that effective teaching can be provided synchronously via the Internet using relatively low cost and low-tech mechanisms. The Internet provides a solution to the problem of providing high quality tuition to remote students. The trial clearly showed that the important factor is the construction of a tutorial that exploits the facilities of the medium; the technical issues (of reliability and immediacy of response) need not be significant problems (and in time better technical solutions will be available). Thus, it is possible, with current low cost technology, to provide a high quality tutorial experience for students directly into their own homes.

Appendix: The Tutorial Content

The tutorial dealt with a topic in Computer Science dealing with the specification of abstract data types. This lends itself well to audio-graphic tuition because it combines graphical notations, mathematical expressions as well as general descriptive matter. The tutorial was based on a typical examination question that the students were expected to have read prior to the tutorial.

The first part of the question asks the student to write down, in their own words, what the meaning of the syntax of an operation, named DATA, of the binary search tree abstract data type. The question gave the syntax as:

DATA: T → I UNION E

and defined the meanings of the sets T, I and E. The expected answer is a brief description of the input (a member of the set T) and the output (either a member from the set I or the set E), and nothing else. In the tutorial, it was possible to point to the elements of the syntax of DATA and describe each feature in turn. It was also possible to state verbally what information should not be provided in the solution to the question.

The second part of the question asked the student to complete certain axioms appearing in the semantics of an operation RIGHT. That is, they should complete the following mathematical statements:

RIGHT(CREATETREE) =
RIGHT(MAKETREE(l, i, r)) =

The two axioms were placed on the whiteboard (from a file) and the participants were asked to give their own solution to each axiom. As usual, some students were happy to try; others were less keen and were asked to simply support (or disagree with) the solutions being put forward. After a short pause while students were typing their responses (which should have been very brief), the expected solution was displayed by the tutor:

RIGHT(CREATETREE) = CREATETREE

and later,

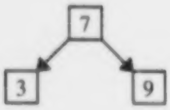
RIGHT(MAKETREE(l, i, r)) = r

Having written down the solution it was possible to analyse them, as a group exercise, deducing a particular pattern exhibited, and hence came to a conclusion about axioms that the students may not have observed previously. The pointing device and oral commentary were invaluable here.

Two more axioms were the subject of the third part of the question and again students were asked to complete them:

INSERT(CREATETREE) =
INSERT(MAKETREE(l, i, r)) =

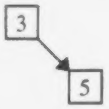
The axioms relate to the insertion of a value, e, into its rightful position within a binary search tree. This time, the solution relies upon recursion and it is particularly easy to reach the wrong answer even when taking a sensible path towards the solution. It so happened that the students chose the right approach and devised the correct solution. Even so, the question gave an opportunity to discuss why the solution is of a particular form and why an uncritical approach could lead to a wrong conclusion. To do this, the following tree was constructed on the white board:



and an incorrect attempt at inserting a value in the tree was illustrated. The illustration was simply by means of drawing diagrams to show the effect of the incorrect 'axiom':

INSERT(MAKETREE(l, i, r), e) = IF e < i THEN INSERT(l, e) ELSE INSERT(r, e)

which is an expression of the idea, 'if the item to be inserted, e, is smaller than the item in the root node, i, insert e in the left subtree, l, otherwise insert it in the right subtree'. In the example exhibited, e had the value 5, and a single application of the incorrect expression leads to the insertion of the item in the left subtree, the result of which is:



Clearly, this result shows e being inserted into the left subtree alone, and fails to 'remember' about the root node and right subtree of the original tree. The correct axiom is:

INSERT(MAKETREE(l, i, r), e) = IF e < i THEN MAKETREE(INSERT(l, e), i, r)
ELSE MAKETREE(l, i, INSERT(r, e))

Placing both the axiom and the example tree on the whiteboard enabled the students to see the actions of the axioms in relation to a concrete example. The ability to create the subtrees as the students watched was helpful in explaining what the axioms were trying to achieve.

The final point, often missed in distance education, is the fact that students main source of information is the written word and they seldom hear the subject being described which not only can be frustrating but also is a common source of misunderstanding (despite the care that we try to take to overcome this deficiency through the use of audio and video tapes). Therefore, a deliberate policy was to describe every part of a diagram or expression in detail.

Proxy Servers and Databases for Managing Web-based Education

Abstract: The World Wide Web represents an information source that could revolutionize public education once difficulties associated with accessing and organizing the information are addressed. Tools to manage some aspects of Web-based information exist, but none that specifically address the needs of educators. We have created an experimental set of tools to facilitate the creation and viewing of topic-specific document collections drawn from the World Wide Web. The toolkit uses a proxy HTTP server and database system and we believe that this combination is a powerful way to solve some of the problems in using the Web for educational purposes.

1. The World Wide Web and Education

Educators need to make available to learners carefully selected information to provide structure and focus to the learning experience as well as to evaluate learning that results from the experience. The Web is a very unfocused arena with almost no structure [Ibrahim & Franklin, 1995]. In order to benefit from the Web's potential, educators must have tools to assist them with the structuring of Web-based material around some foci. Currently, educators' solutions to World Wide Web access for K-12 education fall into one of three categories:

1. *Access to the Web can be completely denied.*
2. *Access can be controlled via a list of 'unacceptable' or 'acceptable' sites. (the blacklist vs. the goldlist)*
3. *Access can be limited to a local Web or intranet that consists only of in-house documents and locally created material.*

If the motive is to provide World Wide Web access within educational settings, the first solution not an option. The difficulty with the second solution is that the lists of sites become out of date immediately. Also, although black and gold lists deal nicely with the problem of unacceptable material, they do nothing to create the pedagogical focus that an educator desires. Finally, despite the educational benefits of local webs and intranets, their creation and maintenance is grossly time consuming and requires significant expertise and computing resources. The resulting intranet may be extremely useful but educators may have to create many materials from scratch, or copy material from elsewhere. A collection of Web documents managed by a proxy server-database combination can provide most of the advantages of a stand-alone Web site, but it does not require educators to create materials from scratch and it can provide tools for data collection to assist with student evaluation.

2. Educational Management

Educators are managers. They manage students, resources and time to create the most valuable learning experience possible. Books, libraries, record keeping tools and timetables help with management of the traditional educational experience, but the World Wide Web provides little managerial help. The Web would be far more useful in an educational setting if it had better facilities for managing students, information and resources.

Student management is essential for meaningful student evaluation, both in terms of appropriate use of resources and skills, and in terms of knowledge gained/practiced while using the Web. Traditionally, student management is documented using paper records, an impossible task for a class of students working individually with Web pages. Some automated form of recording student interactions with the Web is required before educators can really analyze how individual students are using it.

Information management is one of the main tasks of educators. They are trained to select suitable information for a particular set of learners and organize the information to facilitate learner understanding and to maintain focus on a particular topic. Once information is selected for use, the context of the information is set by the fashion in which the material is presented to the students and by communication between students. Selecting information and subsequently sharing the selected information (in its original form) with the learners is difficult when the information source is the World Wide Web. Normally, educators use books known to be written by reputable authors and to contain accurate information. Authentication of web documents is a different matter. Although modern browsers and servers can ensure that the information ultimately received by the browser is the information originally requested, they can provide no assurances that the content of the page is original or accurate. Judgment about the accuracy of the information on a page is left to the user and there is no easy method to determine original authorship of information contained in a Web page. Web documents are unorganized and the educator usually has little control over the context in which learners view pages.

Educators and students have always shared comments and observations about learning materials as part of the learning process. The educator provides guidance to learners as they explore the learning materials. However, sharing comments about Web documents can be difficult, since learners are often working asynchronously and sometimes in isolation. Currently the World Wide Web provides little assistance for shared communication, although some researchers are investigating the use of document annotations as a teaching tool [Roescheisen et al., 1995].

Often, even when a suitable Web page is found for a topic, it may be unreachable (because of network traffic and computer server failure) during the times students have access to the Internet. Even if the document can be reached, increasing network traffic will likely mean that much of the student's time is spent waiting for it to download. The waiting time increases when learners who are unfamiliar with hypermedia systems request irrelevant or unusable documents and then must make additional requests to find usable material. Many educators choose not to use the World Wide Web in an attempt at more effective resource management.

3. Management Tools

Management of Web resources is not a new problem and has been the subject of much research [Maurer & Schneider, 1995]. The solutions that have been proposed for the server side of the Web can be categorized into CGI solutions, special-purpose Web servers, and proxies. Client side solutions, such as Java applets are not considered in this paper.

CGI (Common Gateway Interface) provides a protocol for Web servers to communicate with external programs such as database servers. From an educator's point of view, however, CGI scripts do not provide all the required tools. First, scripts usually must be written by a computer programmer. Additionally, CGI scripts do not always give the educator enough assistance in managing students or resources. Finally, it is difficult to monitor learners using CGI scripts alone.

Specialized HTTP servers, such as HyperG [Andrews et al., 1995], add navigational support to Web pages, monitor user interactions, and maintain a database of meta-information about the documents belonging to the server. Specific-purpose HTTP servers may define a special protocol for communication that could complicate interactions with the rest of the Web. Additionally, the server must be contacted directly from the client to provide its extended services to the learner. Should learners make a request to an alternate Web server they will no longer have access to the specialized navigational tools supplied by the enhanced server. Specialized servers are fine for institutions wishing to create local intranets with limited access to the larger Web, but they are too restrictive and costly for widespread Web access and common educational settings.

Proxy HTTP servers provide both a means to monitor student progress and add navigational links to Web pages. Learners are not restricted to the use of a single Web server while using a proxy. A proxy server combined with a database can provide excellent support for educational uses of the Web. Both databases and proxy servers have been used to address different aspects of managing the World Wide Web. The remainder of this section will discuss some of the current uses of the two.

3.1 Databases

Database systems are already used to store student records. Once the data are entered, automated processing furnishes educators with detailed information about each student. The educator can then construct an accurate representation of what the student has accomplished and discern which material the student has yet to learn. This model of individual students is extremely useful to human educators, but is also useful to computer-based intelligent tutoring systems and adaptive hypermedia systems. A well represented student model can allow an adaptive hypermedia system to tailor the display of a collection of Web pages for individual students [Brusilovsky, 1996].

A conventional database used in parallel with a Web server can provide information about Web documents which have proved useful, or can be used to populate Web pages on-the-fly [Rasmussen, 1995]. Within education, database systems can be used for structuring information about electronic documents to improve their organization. The database system functions much like an electronic card catalog for the Web. Once information about courses (or students) is recorded in a database, a Web-database gateway is used to connect the database to a World Wide Web server. Web-database gateways are CGI scripts enabling communication between Web server and database system. For example, a database gateway could create Web pages containing student progress reports using information exclusively from a database of student information.

In spite of the usefulness of database gateways, there are two areas for which databases provide no assistance. Web-database systems do not ensure that learners work with specific Web pages, and they provide little assistance with data collection because the gateway has no knowledge about which data to collect. A proxy HTTP server can be used both for data collection and access control.

3.2 Proxies

A proxy HTTP server is a computer program that operates as an intermediary between the World Wide Web client and the HTTP server [Altis, & Luotonen,1994]. During a regular transaction between client and server, the client contacts the server directly, requesting a particular Web page. The server retrieves the page (or an error message if the page is unavailable) and sends it back to the client. A proxied communication is similar except that the proxy is in the middle. Thus, the communication sequence is client-proxy-server-proxy-client [Figure 1].

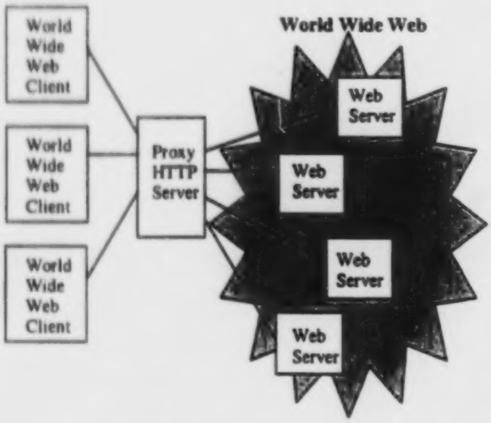

Figure 1: Proxy HTTP Server

Traditionally, proxy servers have been used to improve network performance and to provide secure access for persons using the Internet from behind a firewall. Network performance can be improved because the proxy server can act as a cache for pages that are requested frequently or it can act as a load balancer which redirects requests to less heavily-used sites [Brooks et al., 1995].

Within an educational environment, proxy HTTP servers can serve two functions. They can assist educators in managing information and learners and they can reduce the resources required to provide World Wide Web experiences to a number of learners. The use of a proxy server frees the educator to use any available Web client (browser) and to use Web pages from any server without losing the management features of the proxy. For example, an educator who prepares a structured set of Web pages to illustrate a particular concept usually places those pages on a Web server. Students are given the URL of the collection but may choose to wander off to completely different Web pages on different servers because the educator has no means of ensuring that students use the prepared material. Alternatively, if the learner's Web browser is connected to a proxy HTTP server, each request the learner makes must pass through the proxy. The proxy can be set to refuse the learner's requests for Web pages that are not part of the educator's prepared document collection.

One implementation of a proxy HTTP server locks the learner's Web client to the educator's client, thereby allowing the educator to present a series of Web pages as a 'slide show' which students watch along with the instructor [Yeh et al., 1996]. Similarly, a proxy server can be used to add value to existing World Wide Web pages. A request for the page is made to the proxy which then retrieves the desired page. Before the page is displayed to the user, additional information, often in the form of navigational aides or annotations can be added [Hauck, 1996].

A proxy HTTP server placed on a school's network system not only provides potential information management for educators but it can also act as a cache for frequently accessed documents, reducing the amount of traffic generated from the school and possibly reducing the cost to the school for network access. Proxy HTTP servers can help with information and resource management when educators use the Web as an instructional tool but they do not provide the organizational and record keeping assistance available from a database system. To get support both in managing and organizing World Wide Web information, a combination of a proxy HTTP server and a database system proves most useful.

4. The MicroWeb Toolkit- A Proxy Database Combination

Proxy server-database combinations allow educators to use a database for keeping data about both Web pages and about students. The proxy HTTP server facilitates the collection of the data and can act as a 'librarian' by guiding learners to appropriate materials. It can also augment the original Web page with annotations or other information from the database. The database can store and organize meta-information about the Web documents and the organization of the document collection. A proxy server can collect the desired information about learner skills and knowledge and place it in a database for use by the educator or an intelligent tutoring system. Web resource consumption can be minimized through the use of the proxy's cache and by reducing the number of irrelevant pages the learners request.

Proxy servers have already been combined successfully with a database (in the guise of a separate server) to provided support for document annotation on the Web [Schickler et al., 1996]. Annotations allow learners to share experiences and observations about document collections asynchronously. GrAnT (Group Annotation Transducer) was constructed using the concept of an application-specific stream transducer [Brooks et al., 1995] and a previous prototype for a tool to provide in-place annotations of World Wide Web documents [Roescheisen et al., 1995]. The result is a proxy server that accepts requests for Web documents, authenticates the user before retrieving the document, and adds existing annotations to the document before presentation to the user. GrAnT also allows authenticated users to add annotations to documents. The 'database' for this system was not a relational database system, but an annotation server which provides limited database functionality for this system.

A second system that is similar to a proxy-database system is Interbook [Brusilovsky, 1996]. Interbook is an adaptive hypermedia system that is designed to present individualized electronic textbooks to learners. Interbook collects data about users' interactions with the textbook to make decisions about which part of the book learners should see next. Interbook uses a special-purpose HTTP server, rather than a proxy server. The use of a stand-alone HTTP server adds the requirement that all actions must be directed to the specialized server in order to use the enhanced set of features.

We have created a prototype proxy-database system intended for use in the K-12 school system. Our prototype allows educators to define document collections using any Web documents (from any valid server) and provides facilities for learners to view and annotate those documents. Our software set is called The MicroWeb Toolkit [Thomson, et al., 1996].

The MicroWeb toolkit simplifies the compilation of organized topic-specific hypermedia collections from the World Wide Web. Educators may use existing World Wide Web documents as instructional material while avoiding many of the previously discussed management problems associated with the Web.

A MicroWeb collection is created by an expert Web user using a planning tool, called the MicroWeb Control Environment, to organize the concepts for the topic, to organize documents within the concept web, and to record information about collection documents in a relational database. A completed MicroWeb collection is viewed using an application-specific proxy HTTP server, called the Collection Viewing Proxy, which merges the information in the database with the requested World Wide Web document and sends the result to the user's browser [Figure 2].

Learners may be restricted by the Collection Viewing proxy to viewing only those documents that are part of a MicroWeb collection, or they may be allowed to explore external parts of the World Wide Web. Learners may view documents, follow hyperlinks within the text or from navigational links supplied by the proxy, or may comment on documents by adding annotations. Learner annotations are available for other learners to view, facilitating peer cooperation. By supporting the learner in a hypermedia environment it is hoped that skill in using hypermedia documents will be gained at the same time as useful information is found.

The MicroWeb toolkit, and the combination of proxy-database in general, has great potential within an educational setting. Through the proxy server all learner interactions with a collection are recorded in the database. The educator may use this database information to analyze learner performance and make decisions about future work the learner must do. Learners who work within a document collection remain focused on the subject matter and have less opportunity to get lost in hyperspace because the collection is topic specific. The educator is confident that the material students are working with is accurate and appropriate because it has been selected specifically for the collection. Finally, computing and network resources can be conserved because an entire collection can be cached by the proxy HTTP server eliminating further network traffic unless non-collection pages are requested.

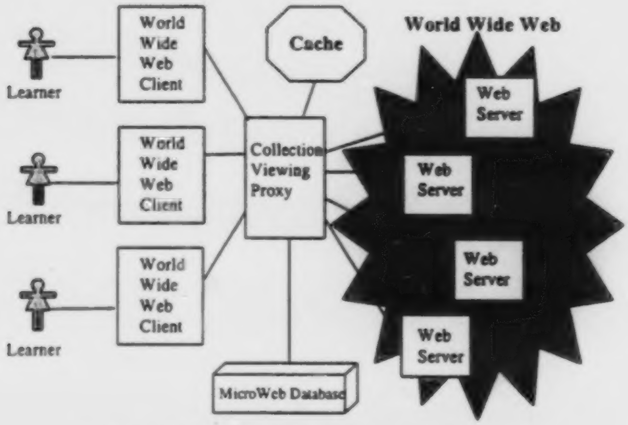

Figure 2: MicroWeb Collection Viewing Proxy

5. Conclusions

The management problems we referred to previously can be addressed by using proxy HTTP servers combined with a database. The proxy server facilitates management of students and information, allowing the educator to monitor progress without physically watching each student, and the database allows organization of the collected information for efficient retrieval. One such proxy database system, the MicroWeb toolkit, has been developed by the authors to expedite the creation of topic-specific document collections using World Wide Web documents and to allow viewing of the created collections on standard Web browsers.

The MicroWeb toolkit addresses many of the problems encountered while using the World Wide Web as an educational resource. It has been used to create sample document collections, and will be evaluated with learners and educators during the summer of 1997. Proxy-database combinations seem to have exciting possibilities for educational Web applications. Because of the ease with which the combination can collect and analyze data, its use could be extended to many other aspects of education.

Abstract: Addressing the potential for trans-national design consortia and international professional consulting offered by the North American Free Trade Agreement (NAFTA), the paper makes reference to the instructional objectives of international architectural reviews and the actual implementation of a "virtual design studio" that brings together Texan and Mexican design students by making use of compressed video technology. As conclusions the paper offers a list of findings that confirm original assumptions, create new working hypothesis, and motivate future research.

Design Studios in Architectural Education

In the curricula of architectural education it is common to find a structural back-bone made out of a sequence of "design studios". Design studios are complex instructional environments oriented towards offering a vast range of hands-on learning opportunities (Angulo 1995). In a design studio, students learn to design by designing architectural objects of increasing levels of complexity until acquiring the knowledge and skills needed for handling complete buildings in a working/learning environment somehow analogue to our professional design offices.

For an observer, a professional design office is an enterprise nourished by the experience of one or several senior architects and their interaction with a body of less experienced design collaborators. In such a framework we may find a wide variety of scenarios that need to be emulated in our instructional design studios. For instance, in a professional design office it is frequent for the senior architect to call upon a collaborator and brief him/her on the requirements and constraints of a new project. Depending on the size of the design firm, it is possible that following such an event that same collaborator may add some requirements to the design problem and brief other design collaborators that will then initiate a study on the subject and start to render design ideas. As design ideas start to emerge, more experienced designers will sit together with less experienced designers for conducting "design crits". Design crits serve as brainstorming sessions for the further development of the project. As the project starts to take shape, design crits will call for the participation of senior designers.

In analogy to the scenario of design briefings and design crits in our professional offices, we have managed to develop similar dynamics in our instructional design studios. For such matter, our schools count with large rooms properly furnished with drawing tables, meeting areas, and pin-up walls that emulate the environment of professional studios. In such environments, a design instructor will meet with a group of 12 to 16 design students for conducting design briefings, design crits, and all the additional activities relevant to the process of designing a building. Instructors will be likely to meet with their students on the basis of 3 times per week, but beyond such schedule students will be expected to develop a complete life style around the development of their design projects and virtually move into their studios.

In some schools the analogy that shapes our design studios has been expanded by introducing the participation of teaching assistants under the direction of senior instructors. In such cases an internal hierarchy of expertise, similar to the one we may find in professional offices is generated. In some other cases, we may find that students of different levels of skilfulness are put together to work on a single design project, and in such way generate conditions for the establishment of team work and leadership.

As a common denominator, in every design studio we can identify the following dynamics:

- Formal lectures in which the instructor stands in front of the students and lectures them on subjects related to design theory making use of a blackboard or white board, an overhead projector, a slide projector, or a data/video projector.
- Seminar meetings in which the instructor and the students sit together on a circle for discussing theoretical and/or ethical issues.
- Design briefings in which the instructor offers a presentation on the design project at hands. The instructor will address design requirements, design constraints, an architectural program, a design schedule, etc. Students are likely to interrupt at any time with questions and/or suggestions as if addressing a client embodied in their instructor.
- Individual crits (also called desk crits) in which the instructor moves from student to student as they work on their projects. Individual students will briefly show what they are currently doing and the instructor will offer individual advise on how to correct design defects or improve design content.
- Peer crits in which students will meet in small groups of 2 or 3 people for reviewing their designs and offer advise to each other.
- Pin-up reviews (also known as informal reviews) in which students will pin-up their projects for any one to see and comment on an individual basis
- Collective reviews (also known as formal reviews) in which students will present their projects to a group of instructors and their peer. Anyone can intervene with questions, remarks, or comments that may hi-light positive of negative aspects of the design.

During a regular semester, a design studio will visit the above mentioned dynamics at least once. In some cases design studios may schedule several design projects per semester or address a large project that calls for the implementation of several formal and informal reviews.

A New Generation of Design Studios

As our profession moves into the use of computer technology, our instructional environment needs to react accordingly, and if possible, anticipate the trajectory of its application in our design offices.

Addressing our need to keep pace with design offices, most schools of architecture have implemented computer laboratories in which students find computer applications for assisting them in the generation of design documents. Drafting programmes have been available for a long time and by now most schools also offer solid modeling resources. Beyond the productive role assigned to computers, there is a slow but consistent move of the profession and colleges of architecture towards the use of computers as actual design tools. "Electronic Design Studios" (Mitchell & MacCullough 1991) are becoming more and more common as we accumulate valuable experience on how to introduce computers in some of the dynamics that define the way in which design studios work.

But beyond the use of computers as isolated tools, or as components in local networks within a single design firm or college, we are starting to see that national and international networks can be used for conducting design related activities. Design firms are starting to make effective use of the Internet for establishing design partnerships. Partnerships that are not restricted to a national context but can actually open doors to the export of our design expertise. This potential is quite evident in Texas and Mexico where due to our cultural heritage we are specially well qualified for addressing our mutual needs and aspirations.

Having in mind the kind of knowledge and skills that our graduates would need to have for dealing with an international design context, and the kind of tools they will need to embrace for such a purpose, we have developed an instructional design studio that seeks to address such knowledge, skills, and instrumental resources.

The Tex-Mex Virtual Design Studio

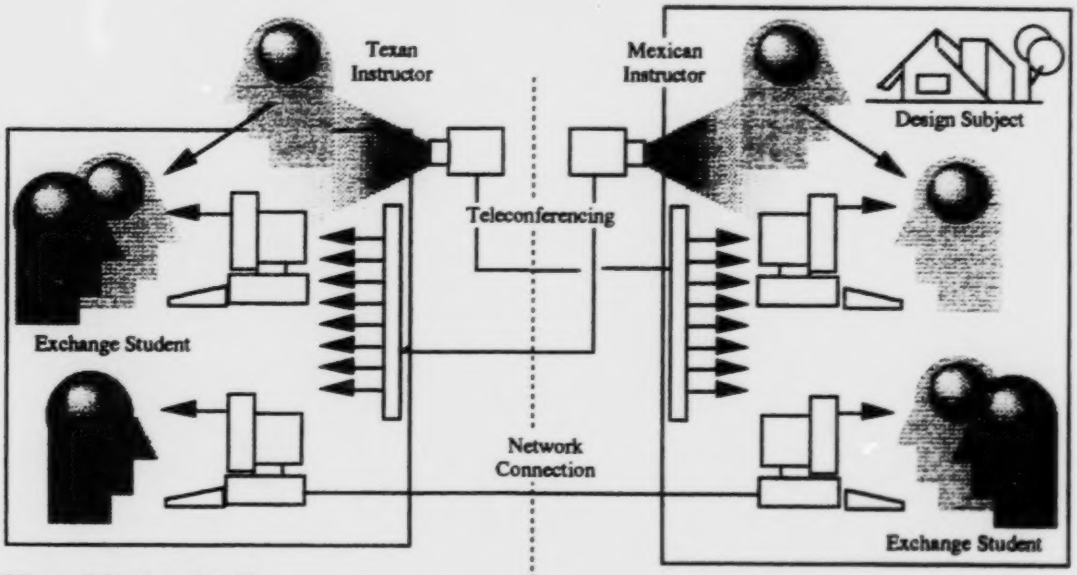
In the process of developing an instructional environment able to address effectively the knowledge and skills required by an architect that seeks to operate in an international computer-mediated context (Vásquez 1996), we

BEST COPY AVAILABLE

started by establishing an international partnership that could emulate such operational conditions. Through mutual agreement in early June 1996 the College of Architecture at Texas A&M University in Texas and the School of Architecture at La Salle University in Mexico City initiated the process of defining the instructional targets to be jointly addressed and the resources needed for supporting the intended dynamic.

From the offset, we all agreed on the need to maintain every single dynamic of our conventional design studios in place. Our intention was to add on our current instructional targets and not to replace them on any way. The instructional targets we decided to add can be outlined as follows:

- Acquisition of knowledge related to the cultural context of our counterparts. The use of a second language was of prime importance in this framework.
- Acquisition of knowledge related to the professional context of our counterparts. Factual information on the environment, building resources, and building constraints were to be given particular attention.
- Acquisition of skills on the use of Internet resources and applications. Initially the use of e-mail, FTP sessions, and WWW documents was foreseen.
- Acquisition of skills on the experimental use of compressed video technology. In particular the unprecedented implementation of international architectural reviews was anticipated.



Virtual Design Studio Dynamic

By the end of the August 1996, two groups of design students of 4th year, one in Texas and the other in Mexico City, were selected for the experience. Initially our intention was to limit each group to 12 students but due to administrative requirements the group operating out of Texas had to be upgraded to 16 students.

In anticipation to the workload to be imposed on students and instructors, it was decided to split some of the added instructional targets. For this purpose it was decided that the official language of the studio was to be English and that the design subject was to be established in Mexico. Under such arrangement, Mexican students were offered the opportunity of practising their English at the same time that Texan students were offered the opportunity of learning more about the cultural and professional context of their counterparts.

The design subject chosen for the exercise was a five stars holiday resort and cyber-colony in the Mexican island of Cozumel. Beyond the implicit attractiveness of the subject and the fact of being immersed in a Mexican context, the subject was in particular interesting because it addressed the question of how architectural objects should make reference to the growing trend of telecommuting from remote locations. Through the chosen design

BEST COPY AVAILABLE

exercise we saw the potential for experimenting with networks at the same time that we addressed an architecture that may help support such dynamics.

The design studio in Mexico City was established on the basis of a traditional design studio instrumented through the use of drafting tables and a model-making workshop. The design studio in Texas was implemented on the basis of an electronic design studio instrumented through the use of computer aided drafting programs and solid modeling programs. Both groups had access to Internet connections and a direct compressed video hook-up.

The first dynamic to be implemented was a design briefing. For such a purpose a compressed video teleconference of 3 hours was scheduled. Following the initial introduction of each student and the instructors, the Mexican studio presented an overview of the location selected for the project and a considerable amount of information referred to the Mexican context. Texan students reacted with a number of questions and interactivity between the two groups became almost as intense as in conventional design briefings.

Following the design briefing and in order to make it possible the implementation of desk crits, peer crits, and pin-up reviews, the students were asked to put up web pages showing their projects as they evolved in time. Student web pages were accessible through course web pages and a large number of remote hyper-links. Many students set their web pages in such a way that they could offer not only a view into their projects but also a view into their lives.

As the content of web pages started to grow, students started to exchange comments making use of e-mail. In this way a dynamic analogue to desk crits and peer crits was implemented and in certain cases a climate very similar to the one typical of pin-up reviews was notorious. As a general rule, the students receiving comments from a peer acting as a reviewer were urged to fulfil the courtesy of reviewing the project of such peer and render a crit of their own. Through this process students became more familiar with each other and came to grasp an initial understanding of some of the many projects that were on development.

For the implementation of collective reviews, 3 compressed video teleconferences were scheduled. Each teleconference had a different objective. The first one was to be somehow informal and cover aspects of conceptual design. The second one was to be somehow formal and cover aspects of building design. The third one was a formal review of complete projects including details and interior designs. Each review was scheduled for a duration of 3.5 hours.

For our first collective review it was decided to use the same teleconferencing facilities that were used during the previous meeting. Our objective was to permit every single student to present their projects and answer questions from their peers at the other side of the line. Thanks to well-controlled timing it was possible to cover all the members of the studio but through such process a number of interesting facts started to show.

In particular, it is worth mentioning that the Mexican site had only one moving camera able to cover the teleconferencing room and a small document camera mounted on a table. Students had been working on conventional drawings of large format and physical models of relatively large dimensions. The problem they had to face was to determine how to put such documentation under the view of their cameras. The resolution of a tele view on large drawings was low and the use of the document camera for viewing the physical models was very time consuming. In this regard there was a clear need to spin the models and be able to see them from different angles, as we would do at the time of moving around a static model.

The Texan site had two room cameras. One was used for a fixed view of the students and the second one was used for focusing on specific students as they presented their projects or made questions. The Texan site also counted with a camera for small size documents. In anticipation to the limitations imposed by the equipment, the Texan students developed most of their work on the basis of small format drawings transferred to overhead transparencies. The main problem with this approach was that the transparencies as exposed under the document camera reflected some of the lights on the ceiling. Furthermore, freehand drawings that look fine at the time of using an overhead projector adopted a childish character when transferred to the video monitor. A number of students had to improvise transferring some of their drawings back to paper in order to offer a better view of their ideas.

On the overall, interactivity between students was far more fluent that during the preceding design briefing session, but the price to be paid came on the form of limited participation from the instructors. During a conventional collective design review, instructors tend to take as much as 70% of the time available for comments and questions, but in the context of our teleconference the instructors were so busy maintaining control of cameras, focus, and audio that their participation became somehow superficial.

For our second collective review the technical set-up in each site was somehow different. In general terms it would be fair to say that both groups managed to get their message across the interface but it was obvious that both set-ups required massive improvement. In particular we can outline such areas of improvement as follows:

- Conventional moving cameras do not render the quality required for the display of large format pin-up drawings. Better results may be obtained by using a hi-resolution camera similar to the one used for small format documents.
- The display of physical models is constantly disturbed by the movement of the model and the consequent effort of the camera to re-establish proper focus. Better results may be achieved by devising a turn-table system on which the physical model could be turned around in a slower and smoother fashion.
- The use of cameras that may feedback on images of the remote location is of fundamental importance during the rendering of a crit. We need to explore ways to improve the quality of the remote image on the feedback and add the possibility of real-time graphic interaction through the use of a whiteboard as video projection screen.
- Audio control is a constant problem due to the background noise of equipment, as for instance data projectors, the movement of people in and out of the audio pick-up areas, and management of different tones of voice among participants. The use of ceiling-mounted microphones or table-top microphones has been unsatisfactory. We may improve the quality of audio pick-up by adding some wireless clip microphones to the general set-up.
- Instructors tend to be anchored to the control panel. The use of a remote control, a wireless clip microphone, and perhaps a movement tracking camera may come to free the instructors from a specific location in the teleconferencing room.

Our intermediate video-review had a strong impact on the design performance of both groups. A healthy competitive attitude was reinforced but shortly after students started to divert considerable attention from the design process into a documentation process. Students felt the pressure of having to show their projects in a more effective way. In a number of instances, design instructors had to discourage students from pursuing fancy documentation at a cost in design quality.

The commitment of the students to maintain up-dated web pages was higher in the second half of the semester. In part this may be attributed to better skills on the handling of network resources and larger availability of design documentation for maintaining a pin-up review. In general terms the tendency of most students was to show their projects rather than to offer a crit to their peer.

The last video-review of the project was mainly a presentation review in which all the participants of the Tex-Mex Virtual Design Studio had a chance to show their projects. The amount of crit that was exchanged was very limited due to time constraints. Following the last video-review of the project, both groups conducted final pin-up reviews in their own schools and documented their projects for final display in the WWW.

For further information, the web page of "The Tex-Mex Virtual Design Studio" is situated at: http://archone.tamu.edu/~ARCH405/

Conclusions

The research and development adventure hereby described has permitted the formulation of the following conclusions:

- In order to maintain the paradigm of an instructional environment that reflects current professional practice, and if possible anticipates technological applications, we need to transfer a number of key instructional dynamics into a computer-mediated context.
- In the domain of architectural education we need to address a growing tendency of the profession towards the use of networks as base for the consolidation of international design partnerships. In particular the potential for Tex-Mex design partnerships and bilateral consulting adventures needs to be addressed.
- Based on previous experiences in the development of "Virtual Design Studios" (Bradford, Cheng, & Kvan 1994), the use of Internet for establishing a fundamental link between design teams has proved to be feasible. This feasibility has been however limited to some of the many dynamics present in the framework of a design studio, namely: desk crits and pin-up-style reviews.

- Based on present experimentation in the context of our "Tex-Mex Virtual Design Studio" we are accumulating substantial evidence that points towards the feasibility of implementing a wide variety of communication dynamics.
- Based on further experimentation in this field it may be possible to prescribe the configuration of instructional environments specially developed for the purpose of offering instrumental base to a new generation of design studios.
- Future implementations of The Tex-Mex Virtual Design Studio during 1997 will target the question of instrumental transparency and output media.

A Model to Assess the Value of WWW-Based Applications in Stimulating Productive Engagement by Students

Abstract: The analysis of factors that affect student's success rate in higher education has a new impulse in The Netherlands, stimulating in particular a focus on what students themselves perceive as critical. The productive engagement of students is defined as working in an efficient manner, with good study habits and intellectual commitment. How can telematics help support this on an university-wide basis? In particular, how can the use of the WWW be oriented around a goal of increased productive engagement? We give an overview of how the IDYLLE Project at the University of Twente is stimulating investigation of these questions.

Improving the Efficiency and Effectiveness of Higher Education at the University of Twente: The IDYLLE Project

The University of Twente is a university with a strong technical orientation and a leader in The Netherlands in the field of telematics, in terms of research, in facilities available to all students and staff, and in terms of use of telematics applications as integral aspects of how we all work. This leadership includes innovative applications of telematics in our mainstream courses, as well as in various experimental course settings and in supporting the research of our graduate students and staff when on projects outside the country [Collis, Andernach and Van Diepen 1997; Pouw, Van der Veen and Andernach 1997]. As part of the University's commitment to its telematics profile, an interfaculty Centre for Telematics and Information Technology (CTIT) has been established, combining both technical and social-application emphases. The Faculty of Educational Science and Technology and the Faculty of Computer Science are major partners in the CTIT. In recognition of the potential of both the CTIT and telematics more generally to make substantial and serious contributions to the social and economic growth of The Netherlands, the Board of Governors of the University has awarded the CTIT a major four-year grant to turn its efforts to the benefit of the university itself: How can advanced telematics applications improve education at the University of Twente in a measurable and meaningful way?

The IDYLLE Project is responsible for this applied research, and has recently completed its start-up year [see Van de Kamp & Pouw 1997]. Among five specific projects and a variety of other initiatives, the Project is involved with developing more effective groupware tools for project management for staff and students alike in the many courses at the University that involve students working in (often geographically distributed) groups on complex design problems [Van der Veen & Collis 1997] and with developing and integrating networked multimedia databases as educational resources so that, for example, video on demand services can extend the lecture in time and location and can link portions of instructor demonstrations to other forms of electronic study materials. Further information about the Project is available from [IDYLLE 1997].

But the IDYLLE Project is more than a collection of advanced-telematics initiatives; it is an integrated research project grounded by an conceptual and empirical analysis of key factors that affect educational quality and productivity in higher education. This analysis has resulted in a hypothesized model of factors that affect the efficiency and effectiveness of the educational process, and in particular that affect the rate in which students complete their studies. One goal is that an increase in the rate of student throughput occurs, without decrease in the high standards expected of students at the University or in the opportunities that students take advantage of to study abroad or to do their final projects in settings outside the University. As a result of a variety of analyses, we have hypothesised students' "productive engagement" as an important component of their rate of successful and efficient completion of their studies [Van de Kamp, Collis & Moonen, 1997].

Productive Engagement: A Critical Student Variable

We define productive engagement as occurring when students, given appropriate instructional tasks and goals and effective supervision and instruction, become mentally involved in their studies, work effectively and efficiently at their tasks with good self-regulation and with on-going self-evaluation. The productively engaged student is not wasting time, not spending too much or too little, but is investing time in a well-organised way so that he not only sees the relationships in the various aspects of a course, but becomes self-motivated to become increasingly professional in his own intellectual behavior. While productive engagement is difficult to succinctly define and objectively measure, the IDYLLE Project is nonetheless taking it as a critical focus, and as a starting point is using the operationalization of "how time is spent in a course" as an analysis variable. If students work efficiently and if the course is appropriately offered, they should be able to complete a course in a satisfactory manner in the time allotted for the course. Does the time they spend pay off for them? If not, why not? Can telematics help?

After various pilots, a survey has been carried out among a sample of 226 students representative of different faculties and years of study, asking the students to indicate from a long list of various factors how much each factor tends to affect their productive engagement of time in a course. The results of the analysis are given in more detail elsewhere [Van de Kamp, Collis & Moonen, 1997] but show three clusters of factors to emerge as most influential from the students' own perspectives: (a) a cluster related to the student's personal level of motivation and interest in a course; (b) a cluster related to the degree to which a course is well-organized and well-integrated; and rated as most important, (c) a cluster related to the student's own study skills.

Interestingly, variables often assumed as important to student performance, such as opportunities for more frequent or more informal discussions with the instructor, and opportunities to study with other students or to be engaged socially with other students in course activities, were not selected by our responding students as having particular effect on their productive time investment in a course. Also, while concerns about personal finances were not seen as having much effect on their efforts, personal time constraints were seen as a serious constraint. While cultural variables may distinguish these students, enrolled in a Dutch university emphasizing the technical sciences and with high demands on its students, from other cohorts, the pragmatic nature of students in higher education has been noticed by us in other countries and different sorts of university contexts.

Relating the Use of the WWW to Productive Engagement

How does the WWW, as one of the current applications of telematics most widely in use at the University of Twente, relate to these three clusters of factors that appear to be important to students' productive engagement? How can the use of the WWW be steered so that these factors are emphasized? We are now identifying examples of WWW applications that appear to be closely associated with these clusters, and doing some first data collection relating to the hypothesis that students' productive engagement in a course, operationalized as spending time productively, can be heightened through applications of the WWW that focus on motivation, efficiency of course organization, and support for better study skills. Following are brief discussions of WWW-based applications relative to each of the three clusters, using two particular courses at the University of Twente as examples. These courses are both for first-year students, one in the Faculty of Educational Science and Technology (called "Introduction to Instrumentation Technology" or "ISM-1"), and the other in the Faculty of Informatics (called "Applications of Information Technology" or "AIT"). Both courses have been re-engineered to WWW-based formats [Collis 1996] [Collis, Andernach & Van Diepen 1997] and can be visited at:

ISM 1: http://www.to.utwente.nl/ism/ism1-home.htm

AIT: http://wwwedu.cs.utwente.nl/~aitnlpbg/welcome.html

Cluster Related to Motivation:

The survey responses indicated the importance of the student's extrinsic and intrinsic motivation and interest in a course to his or her engagement in the course. This was expressed not only in terms of the student's own individual interest in and motivation for the subject of the course and its the particular objectives of the course, but also more indirectly through the value that students attached to perceiving the meaningfulness of a course relative to what actually happens in practice.

The WWW can be a powerful tool for stimulating these sorts of motivation. One way this can be done is already becoming commonplace: through the external hyperlinks that can be supported in a WWW site, the instructor can easily link the students to large repositories of information and current developments relative to the subject matter of the course but also can make these links in a more fine-grained way, directly connected to a particular aspect of the study material or materials describing the assignments of the course.

But showing how the subject matter of a course relates to issues and practice in the real-world can be made even more motivational for students if the students themselves can contribute such examples to the course materials. The WWW provides convenient facilities for such student-contribution to the study material in a course, heightening not only the students' awareness of the application of the course in practice, but also his or her sense of personal investment and engagement in the course materials themselves. Until the WWW there was not such a common and convenient way to integrate student-found examples into course study materials, and for the instructor to link these to existing study materials and to student assignments. An example of this can be seen in the course "ISM 1", in which students fill in CGI forms that indicate the URLs of WWW sites that they have found that are relevant examples of the content being elaborated in the course. These submissions are directly integrated into the course WWW site, and used by the instructor as subsequent study, and even as the focus on questions on the course examination [see also Collis & Meeuwsen 1997]

Motivation can be stimulated in many other ways via a judicious application of the potentialities available in a WWW site. For example, study materials in not only in the modalities of text and static images but also in sound and moving video can be made available to students, increasing the chance of appealing to the various modality preferences of the students. Examples can be seen at the ISM-1 site, not only in terms of links to external sites containing movies and audio, but also in terms of being able to link in movies and audio files made by the students themselves and subsequently used as reference and example material for the course.

Finally, personal interest in a course can be stimulated by using the WWW environment as a tool for new forms of communication and collaborative work. When students can, and must, work collaboratively with others in a different location via a WWW site on some sort of activity meaningful to the goals of the course, the opportunity is heightened for students to feel a sense of personal engagement in the course, and thus, perhaps, a heightened sense of intrinsic motivation and interest in the course. An example of this can be seen in the AIT course, in which students carry out the course assignment by working collaboratively with students in Finland, entirely through the use of different telematics tools [Pouw, Van Veen & Andernach 1997]

Pragmatic Aspects of Course Organization:

From the survey results, two associated subclusters of variables emerged that together we have interpreted as relating to the efficiency of course organization. The subclusters represent two levels of pragmatism on the part of the students. One level relates to efficiency at the adminstrative-organisational level (Can students find the information they need in a time-efficient, location-independent way? Will this information always be up-to-date and the same for all students? Will students have a convenient and timely way to ask a question and get an answer?). All of these relate to the impact of time constraints on the students and their high ranking they gave to "clarity in the course organisation" on the survey.

The other subcluster relates to what might be called the content-related pragmatics of the course. Students want to know why they should be doing a certain activity or studying a certain reading; in a practical way, they want to know what relevance this has to them in terms of successful completion of the course, in terms of their marks. That the students indicated on the survey they highly valued an instructor who could present material clearly may also relate to this desire for "content-related efficiency" or "content pragmatics" on the part of students.

The WWW can be used to emphasise both these aspects of efficiency. In terms of adminstrative-organisational efficiency, the use of a WWW site to provide a central place, where independent of time or access point of one's browser, the student can access any course-related information is clearly a use of the WWW that is gaining in familiarity. The two example courses to which we are referring, ISM-1 and AIT, have both fully integrated all their adminstrative aspects within their WWW sites.

Content-related efficiency, pragmatics, can also be supported through the use of WWW functionalities. The instructor can add links to direct the students' attention to the intended points of interrelationship in a course, particularly interrelationship between theory and examination and assignment-grading criteria, and between practical activities and examination questions. The instructor can also add parenthetical comments to entries in a site, via links, in which the intended relevance of an entry is further described for the students. A description of evaluation procedures and criteria in a course can be linked to the conceptual materials underlying them so that students are reminded of *why* they should learn something or do something to a certain standard in order to successfully complete course assignments or examinations. Exemplars of student work demonstrating good and excellent levels of achievement can be linked to, and used to reinforce instructional points as well as clarify expectations with respect to assignments.

But even while the students indicated their appreciation of efficiency in a course, they gave highest rating overall in the survey to their own study-skills and habits in terms of factors that influence their productive engagement in a course. We discuss some examples of how the WWW can support the development of self-regulated learning and study skills in the next section.

Improvement of Individual Study Skills:

The students responding to our survey indicated their own study skills, their ability to summarize, to structure, to reflect, and to plan and their overall self-discipline as the variables most important to their productive engagement in a course. The WWW can also support the development of these skills in self-regulation in a variety of ways. One is to make available "cognitive tools" of various sorts for the student to use, so that he or she can be reminded, and facilitated, in study habits such as note taking and self-testing. But student self-regulation can also be coached, or "scaffolded", in a variety of ways within a WWW site, depending on how much prompting is given in terms of planning or reflection or other self-regulatory skills. How to do this effectively with WWW sites serving students who are working with the course at different times and in different conditions relative to their learning histories and needs is the focus of a new research project at the Faculty of Educational Science and Technology.

Student Experiences with the WWW: Is Productive Engagement Being Heighted?

The above examples show, in concept, how certain applications of the WWW can be argued as good candidates for the improvement of students' productive engagement of a course. But how can this be tested in practice? So far, we have a considerable amount of anecdotal evidence about student use of WWW environments, and factors that constrain that use, but we are only beginning to empirically investigate the relationship to productive engagement and time investment. From our anecdotal data to date we can note a sample of the reactions of students to our own use of WWW-based course environments that suggest both support for our hypothesis but also the need for its refinement. We list several of these indicators below:

- With respect to the motivational aspects of WWW sites, we have found that the well-structured use of CGI forms for students to enter their own examples and peer evaluations into a WWW site and see those examples integrated into the site, is motivational for students. However, the degree to which they take this material seriously as study material depends on the degree to which we make them responsible for commenting about it on a test or otherwise give them points for their entries.

- With respect to the motivational aspects of integrating multimedia resources in WWW sites, we have not found the students to be particularly interested in them as enrichments to their study materials. Perhaps it is a longer job than what can occur in one course, or even one generation, but there appears to be a assumption on the part of the students that the "real" study material is what is in "the book", that learning from examples and from external sources is not serious learning, nice, perhaps, but not what counts. We have found a similar reaction to external sites that we have linked to in our study materials; although we choose them with care, students do not seem to take them seriously. They are like the old "Extra for Experts" questions at the end of a chapter in a textbook: who spent time on them? This represents a more-deep seated issue with respect to the use of the WWW and telematics applications in education: Perhaps many of the attributes that we as professionals value most and that we now are pleased that we can more directly make available to our students, such as links to external examples and multimedia extensions or more chances to interact informally with us, are not those attributes that students value or even want, at least in early days in their professional development. And this may not be just a function of immaturity on the part of younger undergraduate students: the question "Is more better?" can be asked of our innovations with media and technologies at every level. We have found in other research that the answer to this question is sometimes "no" [Moonen 1994] [Heeren 1996].

- With respect to course organisation, students very much appreciate a sensible and central way to get practical information and announcements about a course, but would prefer that this was not of a nature that they have to print out in order to remember it and use. If information has to be printed, they would prefer it printed ahead of time and handed to them, even though this would mean we would not have the ability to update the material, to add links to examples, or to add other forms of interactivity such as embedded communication possibilities. The major complaint we have about the integration of all study materials in the ISM-1 course site is that students would much rather have these conveniently assembled in a book rather than having to print them; they value their convenience much more highly than the content-related enrichment offered to them by the special features of the WWW environment. Despite our arguments for the conceptual value of interacting with the course study materials on a weekly basis in ISM-1, there has not been much change in behavior with regard to the students' study habits in this respect. Many of the students wait until shortly before a test to begin to study, and then find computer- and printer bottlenecks infuriating.

- This relates to some of our observations with regard to the development of self-study and self-regulation skills, students do not seem to want to be told how to organize their own work and study timing. They do seem to want to know "precisely" what is expected of them. We have found that to help the students become more self-regulatory, we have used the WWW environment to make self-regulation a required part of the course, i.e., that students must indicate their time and work planning (for a small amount of points) and must report on how well they have met that planning, again, for points within the course, as examples of such strategies. Thus we try to convince the students of the content-related efficency of the self-regulating activities by making these relevant to the final mark itself; we emphasize process in our grading, made systematic and visible via the "Group Planning Pages" in the course WWW site, as well as product and "right answers" on the test.

Conclusion: Revisiting the Hypothesis

Our preliminary hypothesis, based on our analyses of factors affecting student completion of courses, on time and to an adequate standard, was "Productive engagement in a course can be enhanced via applications of the WWW". Given the intervening discussion, should the hypothesis be revisited?

Like all simple statements about cause and effect in complex social systems, the hypothesis is provocative but bound to be inadequate without further contextualisation. We suggest a more focused version of the hypothesis could be:

> "Productive engagement in a course, as a function of heightened motivation, efficient and pragmatic course organization, and improved self-regulating skills can be supported by WWW-based applications, but most important are applications that help students to see the relevance of study materials and activities to their final assessment in a course".

As students mature in their professionalism, the latter emphasis on relationship to the mark given in the course can be gradually replaced by the phrase "..to their professional interests", but this replacement is a function of time and career circumstances and cannot be considered as present in the majority of the current undergraduate students. And even as students do mature in their study habits and internal motivation, the pragmatic aspects of more efficient course organization via WWW-based applications may continue to be perceived as more helpful than the aspects of WWW functionality that relate to enriched study resources or extended opportunities for contact and communication. At least, for several more cohorts of students who have been raised with a conception of good teaching and successful learning that places high value on pragmatic and organizational efficiency..

Abstract: We describe ongoing evaluations and new research on the use of telematic tools to support project work in higher education. Practical experience at our University has shown that project work can be implemented using the World Wide Web for many aspects of the project activities. The possibilities will grow with the introduction of groupware facilities in browsers. Among other success factors, the possibility to implement efficient and effective group and course management is essential for a more broad application of WWW supported project work in higher education. We describe a research project aiming at the integration of project management tools in a WWW environment. We will indicate how such educational tools will differ from project management suites for non-educational organisations.

Project Based Tele-Learning

Project-based tele-learning is defined as problem-oriented learning within the framework of a group project that uses telematics support for at least part of the project activities. Project-based tele-learning is an instructional form of considerable value, particularly at the University of Twente with its institutional commitment to the integration of theory and practical applications in high-level technical education. At the University of Twente many courses are project based. In these courses, groups of 5-15 students work on complex problems. In some of these courses the students have a project room available for many hours per week. In those situations only the support of asynchronous telematic tools is needed. In other courses, instructors and students are more frequently distributed in time or place and thus in increasing need of telematic support, to facilitate more interactions and cooperation among participants, apart from a limited number of lectures and infrequent face-to-face meetings with group members.

Collaborative Aspects

Collaborative learning in a problem-based context emphasizes interactions, where students actively participate in the learning process while solving a problem as a group. Not only problem-specific learning goals are involved in project-based instruction [Blumenfeld et. al. 1991] but also cognitive and social goals. [Van Woerden 1991], for example, notes that project-based instruction in higher education involves: a problem as a starting point, with the need to select and apply subject-specific knowledge for the solution of the problem; the contextualization of the project situation as preparation for further professional practice; the need for optimisation of group-interaction skills; and the development of self-responsibility for one's own learning process. Collaboration, defined as separate and shared responsibilities harmonized toward the attempted goal, is centered to problem-based project work. Collaboration requires more than goal orientation: it also involves attention for the social aspects of group process as well as efficient management and coordination of tests and subproducts [Collis and Smith, 1997].

Tele-Projects at the University of Twente

In general, when WWW-based environments in which starting points for communication, information search, collaborative document processing, presentation and evaluation are integrated, and are used in the support of project work, the results at the University of Twente are positive [Collis 1996]. Evaluations that have been performed [Collis, Andernach and van Diepen, 1996], [Bos, Morgan and Kikstra, 1996] and [Pouw, van der

Veen and Andernach, 1997] of the experiences sofar at the University of Twente support the positive results but note that there are many needs and improvements in project support that are still required. For example, while students note being satisfied with the close collaboration and interdependency that can occur both within and between project groups, problems occur with respect to the efficient and effective management of project work. Improvements are needed in the management of workflow, the organization of group resources, and the extraction and organization of key materials for a "group memory" in such a way that they can easily be shared not only by each set of group members but also by the instructor and members of other groups. WWW-based environments are valued for project support, but if management and communication tools are not integrated within the WWW environments they will loose much of their potential functional benefit.

Problems and Responses

Based on the analysis of project-based courses at the University of Twente, we have identified six major clusters of problems with respect to group-based project work, and the "tele-project" contributions we have so far identified that are valuable responses to those problems based on our experiences with them [Tab. 1].

Persistent Problems in Group-Based Project Work	*"Tele-project" Rresponses*
Problems in maintaining course cohesion and momentum as students become immersed in their respective projects	A course WWW site that integrates study materials, project-work support and communication tools, and through which each groups planning and progress can be visible to all.
Problems in motivating and structuring collaboration	Choice of a task (communal development of a common product) and instructional strategy, the "Jigsaw Methodology", whereby each group member has clear and separate contributions to the group, see for example [McManus and Aiken, 1995]. Choice of the strategy of combining local and distant members in each group.
Problems in motivating and structuring communication	Strategy of having a rapporteur in each group responsible for responding to the instructor during weekly "on-line activities" structured by the instructor. Use of an mail archive derived from newsgroup tools integrated in the course WWW site.
Problems in maintaining a "group memory"	Use of shared workspace functionality integrated in the course WWW site (in particular, the tool "BSCW" made available by GMD, Darmstadt, Germany)
Problems relating to instructor workload	Use of graphic tools to produce WWW pages, and the development of the "Milestone Suite" (described in this article) facilitating the preparation of course planning and automatic status reporting.
Problems in organizing and executing self- and intergroup evaluation	Use of a WWW site as the product as well as the process environment. This allows for inter-group comparisons as well as evaluations based on overall collaborative results. Use of an evaluation tool integrated in the WWW site. This allowes efficient registration of student feedback, immediate comparison among subgroups of students, and visualization to the students of the similarities or differences in their impressions of the course from those of their coursemates.

Table 1: Improving the efficiency and effectiveness of group-based project work: Problems and tele-project responses at the University of Twente.

Tele-Projects in Other Contexts

There are many other examples of tele-project experiences outside of the University of Twente. [Dirckinck-Holmfeld 1995] reports on the implementation of project work with distributed students in a course conducted at the University of Alborg, Denmark. She notes communication problems in group processes, similar to those we experience in tele-projects with limited or no face-to-face contact among participants [Pouw, van der Veen and Andernach, 1997]. In an engineering context [Chinowsky and Goodman, 1997] report that the quantity of communications rises in WWW-supported team-work. They conclude that project-management coordination is still to be improved via new strategies for collaboration, information sharing and project coordination. Michailidis and Rada [1996] give an overview of tools available for the support of collaborative authoring tools with a focus on substantive and annotative group-writing activities. [Spenkelink and Vliem 1997] report about the educational use of the shared workspace BSCW, initially set up for research communities. The shared workspace functions well as a group memory, if the workspace is under control of the group, the structure is kept simple and emotionally loaded comments are directed through more private channels such as Email or telephone, thus protecting the addressed from 'public' exposure to criticism. In contrast [Rada 1996] reports limited use by students of shared workspaces. He finds that students seem to prefer to use plain HTML-pages for an overview of the work to be done.

From a review of experiences in the literature as well as our own, we have come to the conclusion that project-management aspects of group work are a relatively weak aspect in both practice and literature. We are thus focusing particular attention in this direction.

Project Management in Project Based Tele-Learning

The management aspect of project based group work is especially important when distributed instructors and/or students are involved in the collaboration. Many combinations of remote and co-present participants exist, for example, a number of distant guest lecturers can be involved in the tutoring of a course. Some students might be involved in projects performed by campus based project groups elsewhere. Other forms are bilocated groups of students in international university cooperation projects. In any of these combinations, project management is important.

Project Management and Tools

From the instructor's point of view the management aspects in project-based group work includes having a good and convenient overview of the progress of all groups, and having effective channels for giving content feedback and remarks with respect to the group's progress. For the project groups, management of the group's interrelated processes is important, especially with larger groups. All group members should have a clear common overview of tasks, deadlines and who is responsible for what. If process-related tasks in the groups are assigned to group members, those responsible for management will, like the instructor, feel the need for an overview of the group process and progress.

For both instructors and group members, management of group (partial) products, and easy access to these products is also important in facilitating their work. Altogether, it appears that a combination of a shared workspace, a workflow tool and integrated communication facilities would facilitate group work best. Convenient ways to link group progress indicators with relevant course study materials, and lecture notes would also enrich the project group virtual work environment.

Examples of Project Management in Tele-Projects at the University of Twente

In the Educational Science and Technology course "Instrumentation Technology 1" for first-year students at the University of Twente, extensive use of WWW functions is made to support the project work of the course and, to link this project work to other course elements [Collis 1996]. The planning for the groups is set by the instructor and visualised in tables with columns for *task, person responsible, deadline* and *status*. As most deliverables are in HTML-format, they are linked from this table when completed, thus facilitating group memory and, both instructor and intergroup evaluation. The "Applications of Information Technology" course, part of the Business and Information Technology curriculum, offers first-year students project work in groups composed of Dutch and Finnish students [Pouw, van der Veen and Andernach, 1997]. In this course the groups have to do their own planning, to be commented upon by the instructor. The planning is captured in HTML-format and available through a link from the so-called GroupCentre table in the course WWW site. In the "Working in Project Teams" course, groups of third-year students of all disciplines work on a design project, using a shared workspace as group memory. The student management of the group uses the software product MS Project to produce a Gantt chart indicating tasks and their interrelations. As part of a Word document this chart is available from the shared workspace for all students and instructors.

"Project Suppport" and "Milestone Suite"

Based on the particular analysis of the experiences and needs associated with project management in courses in Web-based environments, it has become clear that an integrated support is needed, combing the different needs for telematic support. This integrated design, called Project Support, will try to fulfill this need. In the development of Project Support new available functionalities can and will be incorporated. The Milestone Suite will fill in the need for project management both as a support for the instructor and the student members of the project group.

Project Support

In this section, we briefly describe the functionalities of the Suite, the desing approach and the architecture. In "Project Support" we are giving particular attention to the efficient support of high-speed communication, efficient and effective access to appropriate (multi-media) information, and management of group processes and group memory. The Project Support environment will integrate the contributions identified in [Tab.1] with new developments made possible by improved network technology and emerging WWW-based possibilities. In particular we are studying the integration of support for real-time communication during group work when group members are in different locations, and the integration of multimedia databases to link the theory and practice of the courses via examples and other resources.

The approach of the research is one of rapid prototyping, incorporating systematic modelling at several abstraction levels, intertwined and advanced by on-going evaluation. In this evaluation we will work to find out how learners and instructors use telematic support tools. Questions we are asking include: Do advanced telematic tools have an added value for the educational process or will they lead to loss of efficiency due to the number of telematic-based facilities that are difficult to control ? A set of modules for project management is being prototyped. We call this the "Milestone Suite".

Design approach for Milestone Suite

In our research project we are focusing on the group management aspects. Our idea is that a 'Milestone Suite' can make life easier for both instructor and student group management. The final implementation will be closely related to the other elements of Project Support, as described in the previous paragraph. Issues to be addressed by the 'Milestone Suite' are:

- How can the instructor easily set up a "milestone planning", to be refined by the project groups ?
- How can status reports be generated automatically giving an overview of the progress to both instructors and group management ?
- How can instructors and group managers give educationally relevant feedback directly to those involved in tasks that require intervention ?

Giving these requirements, it is clear that in our project we will be modeling and testing tools for a distributed tele-learning community. We will do so, from three different viewpoints:

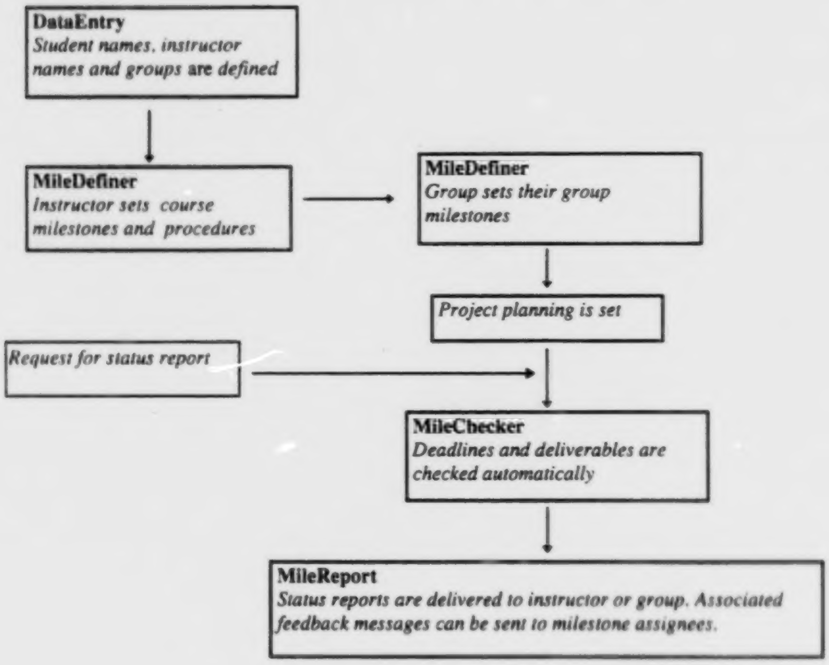
- From the educational science point of view we will use instructional strategies to give us directions on the design of this sort of tele-project education [Collis 1996].

- The formal description techniques available from computer science will be used to model the distributed environment and services needed [Moonen, Michiels, Collis, Widya, 1996], [Volman et al., 1996].
- From the university 'workfloor' we will use the outcomes of ongoing evaluations of tele-learning courses, especially from those courses with distributed learners involved.

Global Architecture

The main modules of the milestone suite are, see also [Fig. 1]:

- DataEntry: Student, group, and instructor data are entered from data sources delivered by the departmental office.
- MileDefiner: The fixed course deadlines, and milestones such as main aspects of a workplan and presentation deadlines are set on a timeline by the instructor. The instructor specifies attributes like EndDate, DeliverableType, DeliverableName, Assignees, etcetera. Also procedural guidance can be made available behind icons on the same timeline. On a second timeline the group can visualise its own group planning.
- MileChecker: When the instructor or the group manager wants an overview of the progress sofar, MileChecker can automatically check if the deliverables are indeed delivered.
- MileReport: The status reports are made to give the instructor an overview of the progress of all groups, as well as an entry point for easy access to the deliverables to be commented upon or assessed. Default feedback texts can be tailored to suit the instructor's needs when sending a message to a group.



DataEntry
Student names, instructor names and groups are defined
MileDefiner
Instructor sets course milestones and procedures
MileDefiner
Group sets their group milestones
Project planning is set
Request for status report
MileChecker
Deadlines and deliverables are checked automatically
MileReport
Status reports are delivered to instructor or group. Associated feedback messages can be sent to milestone assignees.

Figure 1: Global architecture of the Milestone Suite modules.

Discussion : Project Management in the Workplace and the Learning Setting

In preparing students for professional careers, we think it is important that students get experience in working together with fellow students using telematic support. For project-based tele-learning we are giving particular attention to how telematic support can facilitate the collaborative work of distributed learners. We have shown that project work can benefit when supported by a Web-site. Integration of the telematic support functions, communication, memory, workflow and group management will give tele-project education a strong tool. When implementing these functions we will be using mainstream Web-browser technology, combined with tailored software in an integrated, for the users transparent way. Finally, a good educational strategy and a good communication protocol will remain essential ingredients for successful courses using such tools.

Why Computers Are Transforming the Meaning of Education[1]

Kim H. Veltman
Ontario Library Association
100 Lombard St., Suite 303
Toronto, Ontario, Canada M5C 1M3

1. Introduction

The rise of networked computers through the Internet has inspired very different interpretations. Some see it as merely the next step in a long evolution. They note that global communications are not new; that Alexander the Great prepared the way with his pony express linking India with Europe in the fourth century B. C. In this view, the spread of the telegraph and the telephone in the nineteenth century and television in the twentieth century were preparatory stages for the multimedia evolution now underway.[2] Some see networked knowledge merely as an industry driven enterprise.[3] A third view sees the developments of the past decades as the beginnings of a revolution of monumental proportions,[4] a view for which this paper will explore further evidence.

By way of introduction, basic changes in capture and display methods are mentioned. The scope of new content that is becoming accessible is explored, as are the implications of access to these sources in a distributed knowledge framework with respect to collaboration and augmented intelligence. A fundamental development entailing the separation of content and presentation is outlined, as are its implications for the rise of meta-data, agents, delegation of work and the re-definition of learning.

2. Capture and Display

In the past images were captured mainly through two-dimensional photographs Some imagine that computers will merely reproduce these images on their screens, in which case it would simply be a case of translating analogue images to a digital form. Recent developments in technology mean that much more is entailed. First, new cameras (e.g. the Vasari scanner, London) permit scanning at rates of c. 1.4 gigabytes per square meter resulting in much higher resolution than available in ordinary photographs. Second, new laser scanners (e.g. NRC, Ottawa) permit capture of images in three-dimensions such that one can see surface details such as brush strokes, cracks, even subtle surface layers of a painting. In the case of sculptures and museum objects one can produce images in the round which can be rotated on screen such that one can see all sides of the object. Stereoscopic images of these objects can also be created and viewed through lightweight stereo-glasses. Through new methods of stereo-lithography one can effectively reproduce three dimensional sculptures and objects on demand. Third, recent developments in x-ray technology permit one to view different layers of a painting, thus allowing one to trace different stages in the artistic process.

With respect to display of images recent breakthroughs in imaging technology permit one to zoom seamlessly from a distant to a detailed view of a painting. At the high level this requires a gigabyte (of RAM) and an SGI Infinite Reality Engine, as seen in Infobyte's reconstruction of the *Stanze* of Raphael.[5] Hewlett Packard has developed a mid-range version of this technology called Flash Pix and the developer of Apple's Quick Time V-R has produced a low-end version of the same principle called Real V-R. Traditional images were static. The new technologies render these images dynamic and allow the viewer to focus in or move back at will. Such dynamic images challenge the viewer to become more actively engaged in the experience of looking at pictures.

Considerable work is being done on stereoscopic displays in the context of high definition television (HDTV). Another trend is to produce auto-stereoscopic images, which do not require head mounted displays or even glasses and appear as three-dimensional images suspended in space. The net result of such developments is that they frequently allow us to see more through electronic images than we could see in the case of the original object. Thus new methods of display and capture are in fact redefining the very meaning of content with respect to the originals.

3. Distributed Content

In the past, access to materials was limited by those which happened to be available in one's local site. If one had the good fortune to be in a city with a major library such as London, Paris or Rome one had many more resources than if one lived in a village or on a farm. The rise of Inter-Library Loan expanded these horizons considerably on the basis of individual items one at a time. The rise of the Internet saw the emergence of major national networks such as BLAISE (Britain), PICA (Netherlands and Northern Germany) and international networks such as the Research Libraries Information Network (RLIN, which now has over 100 million titles). More recently basic texts linked with the reference section in libraries (dictionaries, encyclopaedias etc.) have been entered electronically and a series of initiatives have begun scanning in the full texts of sections of major libraries. Some of these have been led by major corporations. For instance, IBM is scanning in the Vatican Library, the Luther Library at Wittemberg, and the Edo Museum in Tokyo. Xerox is scanning in the Gregorian Library. In the United States there is a national initiative for digital libraries, which to date involves at least ten projects.[16]

A number of individual museums and galleries have also scanned their complete collections of images, including the national galleries in London, Edinburgh, Ottawa and Washington and collections such as the Louvre (Paris), Uffizi (Florence) and Pushkin (St. Petersburg). Two approaches are emerging. In the United States a short term, pragmatic view dominates. In Washington, for instance, the National Gallery is scanning in its 105,000 images at 30 megabytes an image. In Europe, there is more concern that these images be scanned in once for the long term and at a level such that they can serve the demanding needs of conservators for collaborative, on-line restoration of paintings. Hence, the National Gallery of England is scanning in its images at c.100 megabytes per painting. They have also produced a lower level CD-ROM which has already sold 55,000 copies. The Uffizi, using the Vasari camera mentioned earlier, is scanning its images at 1.4 gigabytes per square meter.

These individual efforts are becoming linked with more global initiatives on a number of fronts. In North America, there are private efforts such as Project Gutenberg and larger initiatives combining private and public sectors such as the Text Entering Initiative (TEI) and the Coalition for Networked Information, which is planning to scan in 10 million books in full text. These projects fit into an American vision, which has both positive features and limitations. Very positive and laudable is their assumption that a basic level of these images would be universally accessible, to all citizens whether or not they are impaired in terms of sight, hearing or speech. Their great optimism about the feasibility of a universal databank of all human culture comes partly from seriously underestimating the scope of the challenge. A keynote speaker at the Sixth International World Wide Web Conference recently (April 1997) estimated that there were 100 million documents in the world. They were not aware that the RLIN database alone has that many titles or that a recent report of the European Commission based on the 75,000 major libraries of Europe (excluding archives), recorded 2.2 (European) billion books, (i.e. 22 times speaker's estimate for the whole world).

Meanwhile in Europe, the European Commission (EC) has introduced a Memorandum of Understanding (MOU) for Multimedia Access to European Cultural Heritage. This includes 282 museums and galleries, 25 governments and regional government organisations, 10 communications service/software companies, 2 Telecom/CATV operators, 22 IT-Telecom equipment companies, 22 members of the new media industry and 24 non-governmental organisations. The goal of the MOU is that by the year 2000, fifty percent of these major collections will be available in electronic form and lead to cultural industries in a new sense.

To this end, the European Commission, within the context of its Advanced Communication Technologies and Services (ACTS) is sponsoring a series of research and technology development projects in three areas: i) interoperability; ii) IPR protection and conditional access, and iii) advanced multimedia imaging, presentation, 3D and virtual presence. The budget for these research projects alone is ECU 812

---

million. In addition, with a view to practical deployment and dissemination the Commission is sponsoring projects under five other initiatives, namely: i) Trans European Networks (TEN) for Telecommunications; ii) INFO 2000; iii) Raphael iv) structural funds under the European Regional Development Fund (ERDF) and v) the Euro-Mediterranean Partnership (MEDA). Some of these themes will be pursued with a greater emphasis on content within the fifth framework (1999-2004).

At the global level, the Bangemann Report inspired the G7 Information Society Exhibition (Brussels, February,1995). This prompted the seven leading economic countries of the world to initiate eleven pilot projects among which are education (pilot project 3), libraries (or Bibliotheca Universalis, pilot project 4) and museums (or Multi-media Access to World Cultural Heritage, pilot project 5). Efforts are underway to co-ordinate the MOU initiatives at the European level with those of the G7 at the global level. For instance, the MOSAIC project within the TEN framework is being proposed as a participant in G7 pilot project 5. There is also some discussion of creating a common front-end for all eleven of the G7 pilot projects.

Very few persons have understood fully the implications of these developments for problems of bandwidth on the Internet. Traditionally the typical connect time for a (voice) telephone call was c. 3.5. minutes. In 1996, the average connect time for a typical user of the Internet was estimated at approximately 35 minutes. There is now much discussion about the advent of the Network Computer (NC). Implicit in this arrangement is that the user needs to be on-line continually. For an average employee that would be eight hours per day. Let us assume that a typical user makes six calls a day, which would be about 21 minutes of connect time. Even an elementary knowledge of mathematics suffices to realize that if the estimated 40 million users all changed their demands from 21 minutes to 480 minutes there would be nearly a twenty-threefold increase in connect time. The use of stereoscopic HDTV, mentioned earlier, would require c. 55 megabits/second, and again dramatically increase the demands.

At present, a typical private user has a 28,800 baud connection. Operational research networks such as the Tuscany MAN, the Canadian Advanced Network for Research Industry and Education (CANARIE) and the U.S. Very high Bandwidth Network (VhBN) are operating at speeds between 45 megabits/second (OC3) and 155 megabits with a view to moving to 622 megabits/second. In April,1997, Pacific Bell introduced commercial services at 270 megabits/second. Meanwhile at an experimental level Nortel has already done a test demonstration at 6.2 megabits/second (OC 192). There is discussion of terabyte networks. The details of such numbers are not important for our purpose, which is to make a fundamental point. The network(-ed) computer revolution is something much more than a simple re-use of our old telephone and television lines. We need to re-connect the world with new networks of wires, and frequently in some combination with wireless modes. Establishing this network will be one of the major growth areas for the next generation. Maintaining this network will be a more lasting source of employment and business.

4. Distributed Views and Collaboration

One of the initial inspirations behind the Internet was not so much the simple on-line access to materials, but rather the possibility of being able to share distributed views at a distance through collaborative work. In 1952, some forty-five years ago, Douglas Englebart, the visionary pioneer who invented the mouse foresaw i) a version of e-mail which would be hyper-linked with ii) shared files, iii) a journal (library) and iv) external (offline) documents.[7] Engelbart's original vision centres on five words, Concurrently Developing, Integrating and Applying Knowledge, a process which he abbreviates to a single term, CODIAK.[8] This process, which comes from a direct sharing of information would be impossible in earlier learning environments such as a traditional (unwired) classroom, a library or a museum. Engelbart sees this process as the basis of an augmented intelligence.

In terms of profession and personality, Douglas Engelbart is worlds apart from Howard Rheingold, the author of *Virtual Reality*[9] and *Virtual Community*,[10] a founder of the WELL, of *Hot Wired* and more recently, *Electric Minds*. In terms of basic approach, however, there are some striking similarities. Rheingold, for instance, tells a story of an event that convinced his wife of the value of his seemingly excessive "surfing." One evening, their daughter was inflicted by a tic. His wife rushed out to find a doctor. Howard went on line and asked for help. Before the doctor had arrived someone on the web had provided necessary knowledge about what to do under the circumstances. At a very practical level this is an excellent illustration of augmented intelligence as described by Engelbart.

It is instructive to note that these views of augmented intelligence are very distinct from notions of collective intelligence, which have been popularised by other recent authors (e.g. Levy[11]). Augmented intelligence is about persons sharing their particular knowledge to arrive at new insights. It is about the development and deepening of individual personalities. They may work together. They may form teams but they remain individuals. Indeed their individuality grows in the process. Collective intelligence, by contrast, implies that the intelligence lies abstractly in a collective group rather than in a concrete individual. In this view the individual as such is implicitly flawed until they are networked in a group which is somehow the locus of this elusive new intelligence. In this view the group is more important than the individual and in some mysterious way the collaborative efforts of the group are held to be more valid than those of an individual on their own. Those who study history may see more than passing resemblances between these two approaches to intelligence and the debates of a century earlier between Kierkegaard (the individual is the locus of truth and development) and Marx (the group or masses are the locus of truth and development). Students of history may also remember the pitfalls of setting groups above individuals encountered in the 1930's.

Augmented intelligence, in Rheingold's view --and implicitly Engelbart's also--, entails a web, which is much more like a telephone than a television: i.e. it is an active experience for sharing and collaboration rather than simply a passive object which provides one with information pre-sorted by someone else. This is rather strikingly different from an emerging market driven view of the web, which typically speaks of cultural industries and collective intelligence. One is tempted to dismiss these differences as merely academic distinctions. It is true the extreme version of the exclusively market driven view is more prevalent in universities than in the frontiers of high industry. Nonetheless, the implications of this view are anything but academic. On the industry side its proponents almost invariably speak of (active) information service providers and (passive) consumers. Rhetorical reference may be made to interactivity, but only in the sense of passive users following choices made by active producers and providers. In academia, the most extreme proponents of this view pretend that business school is highest in the echelons of (academic) subjects and that only projects which bring in money are legitimate, as if scholarship were a straightforward money making proposition. More subtle proponents of this view favour collaboration almost for its own sake. In education this is especially true of the constructivist school, who hold that learning is essentially about creating world views which they believe is fostered by collaborative work. They see the work of groups as more important than the solid thought, reflection and writing of individuals. Hence those who do work in groups are favoured over those who work in "isolation."

Underlying the differences between augmented and collective intelligence are, in fact, two competing views of the web and its functions. At first sight, it might seem that this conflict is a simple one between realists who recognise the importance of economic facts, and idealists who have forgotten that they are living in the real world. It is important to realize that the real battle lies elsewhere. It is not a question of economics vs. an uneconomical approach but rather a battle between an exclusively market driven view and a gift economy. Extreme versions of the market driven view depart from a two-fold business case scenario which a) believes that everything can be reduced to a business proposition in the form of a transaction or b) that one can at least control everything through licenses which are bought. Unfortunately these assumptions do not apply to culture.

In geometry, one of the ways to proof is to assume that a given claim is true and then follow its consequences until the absurdity of the argument reveals itself. Applied to the topic at hand, this approach might run as follows. Business case one assumes that everything can be bought and hence everything has a price. On the surface this is right. One can point, for instance to a very famous manuscript such as the *Evangel* of Henry the Lion, which was auctioned in London a few years ago for over eight million pounds. This manuscript is now shared by the Herzog August Bibliothek in Wolfenbüttel and the Bayerische Staatsbibliothek in Munich. The library of Duke August of Lower Saxony was once the greatest in the world and has had Leibniz and Lessing among its librarians. It has c.12,000 manuscripts and c. 810,000 books, many of them unique copies. The *Evangel* is a special case. At our hypothetical bargaining table we could agree that the average cost of a precious manuscript is much less than the *Evangel*, say one million dollars. The cost of the manuscripts at the Duke August Library would thus be 12 (U.S.) billion dollars. Books are much less expensive. Some may be ephemera. Some books such as a Gutenberg *Bible* can easily be worth a million for a single volume. At our bargaining table we might decide on a bargain price of a 10,000 dollar average per book. The 810,000 volumes would thus be available for a mere 8.2 (U.S.) billion. The manuscripts and books together [12]would cost 20.2 (U.S.) billion. In addition, there are also some 20,000 maps, 26,000 portraits, 950 precious books hand painted by some of the most famous painters of the twentieth century, archival materials, a music collection, a reference collection of 210,000 books. These are all housed in three buildings one of which is a unique historical monument, another of which was the former home of one of Germany's greatest poets. In the interests of brevity these might be lumped together for an additional 4.8 (U.S.) billion, which means that this single famous library would be available for a round sum of 25 (U.S.) billion. This amount is close to the price paid for some of the most dramatic mergers of the past decade, which are also the greatest mergers in history.

In the corporate world, mergers typically occur between two giants in a field where the number of others is seldom more than a half dozen. In the world of culture, matters are very different as becomes clear if we pursue our argument. The Vatican Library, for instance, has c.150,000 manuscripts. These are no less precious than those of Wolfenbüttel. By the market standards established above, the Vatican's manuscript collection could theoretically be bought for 150 billion dollars. Its million books would readily be worth another 20 billion and the secret archives would easily be worth another 30. The map collections, decrees, coins and other artefacts in the library would make another 100. That makes 300 for the library alone, which is part of a much larger complex. Saint Peter's with its inestimable treasures would readily be worth another 300. The Sistine Chapel could fetch 50 as could the Stanze of Raphael and the Borgia Apartments. The painting gallery would easily be worth another 100, as would the Ancient sculptures. Lesser collections such as the Egyptian, the Etruscan, the Chinese might go at 50 each. Even omitting the great hall of maps, the halls of tapestries, and other church objects, the Pope's apartments, the other administrative rooms of the College of Cardinals, the gardens, or the great courtyard and balustrade of Bernini, the radio station, the quarters of the Swiss guards, we have arrived at a figure of 1.15 (U.S.) trillion dollars. Hence a serious offer for the whole complex would need to be at least 2 trillion (U.S.) dollars. As a single expense this exceeds the budget of any corporation and even any government. In the context of Rome, however, the Vatican does not comprise even 1000th of all the treasures of the eternal city. At a conservative estimate therefore, serious bidding for the culture of Rome alone could begin at a sum above 2,000 (U.S.) trillion dollars. The culture of Rome does not amount to a 1,000th of the whole of Italy even if one limits one's horizons to high culture. So a reasonable bid for Italian culture might begin at a sum above 2,000,000 trillion U.S. dollars. Small wonder then that an individual who paid over 30 million for 72 of Leonardo's 6,500 pages was not taken seriously when he offered 2 billion for the images of French culture, which does not deem itself to be inferior to Italy. The point of this excursus is a simple one. Even if everything could be bought, we would rapidly have to conclude that no individual, no corporation, no consortium or even the richest government could even attempt to consider purchasing the cultural heritage of even a single, major European country, let alone the world as a whole. This is a domain where notions of possession, take-over bids and stock options will not work. The notion of buying content may apply to evanescent films but it cannot apply to culture.

Having conceded that we cannot own everything,[13] business case two assumes that licensing for control is the answer. Licenses are typically some fraction of the full cost for a limited term of say five years. In the business world, a license for one percent of the original would be very conservative. Keeping with our hypothetical assessment above, a license for the whole of Italian culture would thus amount to a mere 20,000 trillion U.S. dollars, payable once every five years, which is still considerably beyond the budgets of even the biggest players. In short, the extreme view of business whereby everything can be either bought or licensed cannot apply to culture. It is a myth.

That business cannot own or control culture, does not exclude their working together. If business invests x dollars in scanning the images of a museum, they can fairly expect that when the museum makes money from the resulting electronic images, then the business will be re-imbursed. Business will have indirect incentives for doing so also. Cultural content has great appeal. Almost everyone has some interest in Leonardo's *Mona Lisa*, or Michelangelo's David, or at least would have us believe that they are. With a greater amount of culture more persons will need computers and more persons will use Internet lines (phone, cable, wireless etc) in order to connect with great repositories of culture. Culture provides one of the whys for the products of computer firms and telcos.

This scenario becomes even more attractive if viewing low level versions of the images is available at no costs (other than the transmission) and payment is associated with detailed versions, printouts as postcards, posters, slides, sculptures on demand, special interpretative projects (e.g. films) as well as obvious adaptations for advertising. Once the content is available and there are tools for its publication and interpretation, then there are large new markets for machines and pipelines, and new services in terms of training and maintenance. Some clues for reaching this goal may lie in what appeared at first to be an opposing view.

If the view espoused by Engelbart and Rheingold could seem overly idealistic and ultimately unrealistic, it should be noted that one of its most articulate champions is also one of the paragons of capitalistic, entrepreneurial, free-market business, namely, Apple Computers. Some of the leading spirits at Apple note that Apache, one of the best examples of server software available today is a result of volunteer co-operation rather than from a commercial company and is available free of charge. They also point out that when Apple was developing the programming language, Smalltalk, they came to an impasse due to lack of funds. An estimated two million dollars would have been needed. They decided to make the code freely available and within six weeks, volunteers had accomplished without money that which had seemed economically impossible.

Such experiences led Apple consciously to contrast a narrow, strictly market driven, money economy view with their notion of an educational object economy, which as they are well aware, is based on the principles of a gift economy. Their idea is simple: create an Apple Application Tool Kit, which would effectively serve as the first letters of a software alphabet. A user wishing to adapt letters *a*, *b* and *c* of that alphabet with their own letters *d* and *e* in order to create a new product, would be at liberty to use them at no cost. The proviso would be that they submit the resulting product in the free repository. On the other hand, persons wishing to charge for their results would be charged proportionately for the pieces they acquired from the repository.

The Apple initiative can be seen as part of a larger global trend. Visionaries at Apple such as Steve Cisler, are actively studying the phenomenon of communities, not just the virtual communities of which Rheingold speaks, but the underlying principles which inspire persons to work together. This topic also being studied by the (Marshall McLuhan) Global Village Conference (Franz Nahrada, Vienna), which is becoming a focal point for the emerging field of intentional communities, namely, groups of persons who have deliberately chosen to live in a place rather than simply moving into a neighbourhood by chance.

At the same time the Apple approach relates to the philosophy of freeware on the Net, as in the GNU[14] project of the Free Software Foundation. It consciously builds on principles introduced by some of the developers of Java applets[15] and relates closely to a growing trend toward open standards. Ironically, Apple which initially began in opposition to the legacy systems approach of the old IBM, went on to develop its own proprietary software. IBM then played a key role in founding the Object Management Group (OMG), which developed the Common Object Request Broker Language (CORBA). The Open Group (which sponsors the Open Software Foundation, and the X/Open Group), the Open GIS Consortium, the Open Microprocessor Initiative, the Office of Open Information Interchange (OII), the World Wide Web (W3) Consortium and G7 pilot project 2, Global Interoperability, have the same stated aims. A next challenge lies in all these bodies agreeing on a single corpus of core standards, which will make the universality of the Web a reality.

When we use a telephone, we think of it as hardware. Actually it is both hardware and software. Yet we never think of buying another software package every time we want a new feature. We pay a standard rate and then more for features. Needed is a consortium between the telcos, computer manufacturers, television companies and other players to produce a set of tools which work seamlessly. In the case of digital television[16] there is talk of a 10-20 year transition period in moving form analogue to digital methods. If we begin now with practical tests involving actual users in classrooms and research sites as well as in trial homes, then a universally acceptable and useful interface can evolve in pace with the transition.

As for the new content that is needed, it is instructive, in this context, to recall that the great breakthroughs in content production during the Renaissance would almost certainly have been impossible if tens of thousands of monks working in mediaeval monasteries had not spent centuries preparing source materials in intentional communities on a volunteer basis. In the Middle Ages, these extraordinary efforts were possible because a great percentage of the population was effectively unemployed. A number of futurists are predicting a similar trend towards unemployment in the near future.[17]

One of the most dramatic of these scenarios was explored in November of 1995 in a meeting with 500 world leaders organised by Michael Gorbachev (San Francisco). Here the claim was made that, with advances in technology, within a generation 20% of the population will be employed doing regular jobs and 80% will be unemployed. Their proposed solution was that these new masses of unemployed be distracted with a variant of the Roman tradition of bread and circuses with sex added, "tittytainment".[18] While, it is tempting to dismiss this merely as excessive pessimism, wrapped in bad taste, it is sobering to note that the non-fiction account of the meeting has become a best seller in Austria and Germany and very much *a cause célèbre*. A much more attractive scenario would be a revival of the learning dimensions of the monastic tradition without the dogmatic excesses. Thus one could use an enormous new voluntary work force to arrive at new organization, interpretations and insights concerning culture which will be of benefit to all.

Such a revival of monasticism could also address another fundamental problem. Thus far much of computer software has been designed for business activities which did not exist prior to computers, work flow diagrams, new levels of financial planning, retirement programs and the like. They are sold on the pretext of saving time. Unfortunately they computers save time with respect to distractions they have in turn created. Where are the programs that help us gain serious access to world knowledge, help us to understand the reasons for alternative explanations to truth, philosophical insight or religious inspiration? For economic reasons, computers have addressed business needs more than human ones. A revival along monastic lines could redress the balance.

5. Separation of Content and Presentation

In the world of books there has been a traditional separation between the process of writing the content of a book (author) and the presentation tasks in preparing it for publication (layout person, typographer, editor, publisher, printer). Even so the product of these efforts was traditionally a book in which these processes of content (creation) and presentation were intertwined. In the 1960's and 1970's, those at the frontiers of electronic editing recognized that in the new medium these two processes could be treated as separate functions. To this end a Standardised General Markup Language (SGML) was developed.[19] This became a standard for scholarly groups such as the Oxford Text Initiative and the Text Encoding Initiative (TEI) and was adopted by major document management firms such as Xerox and Intergraph.

Critics complained that SGML was unnecessarily complex. To an extent they were right. SGML was designed for dealing with the complexities of a) high-level scholarly publishing (footnotes, diacritics, accents, special characters in Old English, multiple notations) and b) the sheer volume of a major corporation such as Boeing, which produces manuals weighing more tons than the 747s they describe could lift. These tasks require(d) subtleties well beyond an average user's needs. Hypertext Markup Language (HTML) offered an alternative much closer to these everyday needs and enjoyed a meteoric rise. HTML was also an informal stopgap measure rather than a methodical solution. It conflated the distinction between content and presentation which SGML had laboriously distinguished.[20] The World Wide Web (W3) Consortium is committed to provide more felicitous solutions. Those with complex needs will continue to use SGML. For those with everyday needs, the team at W3 is creating a simplified version of SGML called XML (Extensible Markup Language). To meet the different presentation needs the team is developing cascading style sheets. In the near future it will be possible to have a single content document, which can then be presented and published in the form of many different "views", including versions accessible to those impaired visually, vocally or aurally.

In the short term, the W3 Consortium is working with industry partners to produce tools for four specific markets: web publishing, intranets, electronic commerce and education which includes training. The vision of Tim Berners-Lee is that fulfilling these short-term needs will help realize the long-term goals of personal empowerment, social efficiency, understanding and harmony and exploiting computing power in everyday life to solve problems and augment the capacities of persons.

6. Meta-Data

These tools entail much more than easier and faster ways of producing web pages. They entail new methods for getting at the already enormous mass of information existing on the web which is increasing daily. The earliest search engines either surveyed URLs or searched the full contents of the web-site. The first of these strategies was typically too imprecise or summary. The second strategy is increasingly too cumbersome. Browsers provided an alternative approach by creating personal classifications of terms in hierarchical lists as an intermediate step to searching materials. Until recently there was a clear distinction between search engines and browsers. A search engine such as Altavista allowed a user to choose a term, which would produce a number of hits. A browser such as Yahoo allowed a reader to browse through predetermined lists of subjects hierarchically arranged, choose a term and then call up the associated hits. More recently new tools such as Infoseek,[21] and Webcompass [22] are combining the features of search engines and browsers. A reader types in a term. The search engine finds a series of hits and also a series of related topics, which can be browsed in order to arrive at further hits. The Stanford Digital Libraries Project[23] is developing this approach with new tools such as SenseMaker.[24] These are but isolated examples of a larger picture.[25]

URL, URN, URI ISBD-ER	MIME Types	Site-Mapping	Content Mapping	Abstracts	Library Meta-data	- Content - Negotiation	PICS

Figure 1. Eight ways in which information about information is helping the quest for understanding on-line materials

New tools are focussing on providing information about information, generally termed meta-data, tagging original documents to produce the equivalents of brief summaries, such that search tools can scan these without having to read the full contents at every turn. These include at least eight different kinds of initiatives (fig. 1), which range from short term stop-gap measures to long term solutions. The most basic of these entails adding greater precision to the initial header to the information. One initiative, led by the W3 Consortium, entails supplementing the convention of a Uniform Resource Locator (URL) with a Uniform Resource Name (URN) and a Uniform Resource Indicator (URI). Meanwhile, the library world is creating an International Standard Bibliographic Description for Electronic Resources (ISBD-ER).

A second step, in which Xerox is playing a significant role, entails a more systematic definition of media types, or MIME types. Suppose, for instance, that a user is searching for databases on ecology. Assuming that databases are identified as a media type, then a search can go directly to sites with databases and can skip all other sites where databases are lacking.

A third initiative, involves some measure of quantification using visual tools. To this end, James Pitgow, a student at Georgia Tech, --now at Xerox PARC--, developed a method of mapping the links between a home-page and the hierarchies of topics connected therewith, inclusive of hyperlinks among sections such that one can discern which pages are crucial in any given site. This permits one to see at a glance whether the home page is merely a façade to a few random pages or an entry point to a large body of systematically organised material. This concept of site-mapping will soon appear as a new product of Microsoft.

Related to this is a fourth action, which might be called content-mapping. In the case of databases, this would gather data about the parameters or constraints of the information contained therein. This might, for instance, explain the temporal limits of the materials, that it is only between 1850 and the present; or the geographical boundaries, that it covers only North American materials. Such constraints will also become part of search strategies. For example, when one specifically wants news about Amsterdam, then it would make sense for a search engine to focus on what resources Amsterdam has to offer rather than searching all the web sites on the other four continents at the outset.[26]

A fifth set of steps entails tools to provide automatic abstracts of content. For example, as part of its Application Tool Kit, Apple is working on a product called Vespa, which will serve as an editorial aid for summarising documents. Special algorithms will allow one to have a one page summary, a one paragraph abstract or even a single sentence outline of an article. They are also developing a product called *Hot Sauce*, already on the web,[27] which allows hyperbolic hypertextual linking and editing. In the longer term such initiatives relate to a bigger picture being developed at Xerox, which distinguishes between four elements: the infosphere, workspace, sense making tools and the document. Xerox PARC is working on various new methods of information visualisation.[28] Some immediate implementations are being spun off through a new company termed Inxight, while they continue to work towards a long-term solution. They have, for instance, developed search strategies using a scatter-gather method, which go beyond the simple keyword searches prevalent today. Another group in Grenoble is focussing on digital library solutions.

Loosely speaking all five of the initiatives listed above can relate to meta-data in general, i.e. producing information about information. A sixth set of initiatives, which we can term library meta-data is building on the cumulative experience of the library world and scholarship. In 1995, the Online Computer Library Company (OCLC, Dublin, Ohio), in conjunction with the National Center for Supercomputing Application (NCSA, Urbana-Champaign), organised a first meta-data conference. This resulted in the so-called Dublin Core[29], a set of twenty essential terms (names of fields in databases), whereby libraries could share data about their data, effectively creating the potential for interoperable pointers to works and their contents.

A second meeting in Warwick, England[30], (1996), produced "the Warwick Framework: a container architecture for aggregating sets of meta-data."[31] This discussed more closely the problem of interoperability between different catalogues, which may use alternate words for the same term. For instance, one library may have a field for "Author", whereas a second library has a field for "Name," while a third has a field for "Artist." A person searching from a remote site for literature on Michelangelo has no interest in checking what the variant heading happens to be in different libraries. They simply want the system to search seamlessly in the appropriate fields to acquire the relevant literature. The Warwick framework raised awareness of this problem and prepared the way for a solution.

A third meeting in Canberra (March 1997), focussed on three items:1) a syntax for element refinement; 2) a scheme to record how this term is encoded, e.g. the Library of Congress Subject Headings (LCSH or MESH which could potentially permit links to different classification schemes) and 3) a tag to qualify in what language it is. Participants of these meetings span a large range of individuals from the library world, major industry and governmental institutions. Taken together these initiatives for meta-data promise a new set of intermediary records which will be the equivalent of abstracts on the Web so that we do not have to crawl literally through the full texts of documents which may not interest us.

A seventh set of initiatives focusses more on rules for exchange of content. The Warwick framework explored the concept of discovery packets, as well as permission to use packets and procedures for an issuing agency. The W3 Consortium is also working on meta-data tags for Intellectual Property Rights (IPR), terms and conditions, access control, and information about people, objects (and presumably places).

Finally an eighth set of innovations is focussing on the quality rather than the quantity of the information. For instance, the introduction of digital watermarks both visible and invisible will allow libraries and museums to authenticate their images and track their usage. IBM has introduced this into the Vatican Library project. The Platform for Internet Content Selection (PICS), another W3 Consortium project, initially developed to provide a rating system for parental selection (analogous to that which the V-Chip purports to do), is being broadened to cover endorsement in general. A parallel project, in the form of Java applets will produce Digital Signatures (DSig), which will permit signed metadata and thus provide the foundations for a certificated web. In the world of traditional print we are well acquainted with rating systems ranging from the stars in a Michelin guide, a movie review or a hotel front. Tools such as the above will help us to integrate these functions into tools for the Internet.

7. Implementations and Developments

Ideas are fascinating. They need to be implemented in order to change the world. Serious implementation requires a critical mass of followers such that the ideas can truly become universal standards. This is happening in the case of meta-data.[32] Support is coming from four main areas: libraries, government agencies, industry and the military. (fig. 2). The OCLC/NCSA Dublin-Warwick Framework is co-operating with the largest U.S. database in the library field, namely, the Research Library Information Network (RLIN) of the Research Library Group as well as the Library of Congress, which has been developing the Machine Readable Bibliograhic Information (MARBI), Machine Readable Card (MARC) formats and the Z.39.50 protocol. In turn, the Z.39.50 protocol has been accepted as the Gateway to European National Libraries (GABRIEL) and has the support of the International Federation of Library Associations (IFLA), which has become a reference point for many of the metadata resources.[33] At the international level also, a representative of G7 pilot project 4, Bibliotheca Universalis, has been following the meta-data developments

- A. International Standards Organization (ISO)

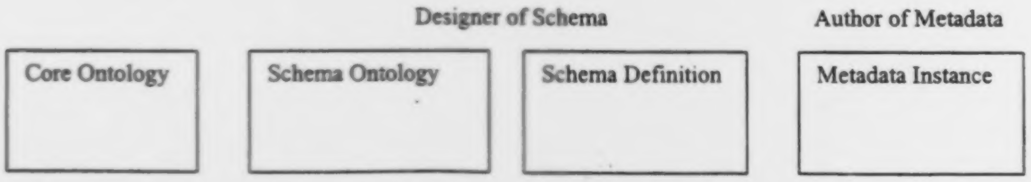
- E. Major Companies
        - Xerox Metaobject Protocols[45]

Figure 2. Some of the key players in the field of meta-data.

As for the military, in the United States, for instance, the Defense Advanced Research Projects Agency (DARPA), is extremely active in this domain. It has introduced concepts such as Knowledge Interchange Format (KIF) and Knowledge Query Markup Language (KQML) and has initiated an ARPA Research Program on National Scale Information Enterprises. In terms of industry, the efforts co-ordinated by the W3 Consortium have already been mentioned. The Open Group is also actively studying meta-data. Perhaps the most articulate public statements have come from Apple, who have published a call for a Metadata Framework.[46] Other companies such as IBM, Xerox and NEC are using metadata in their quest to establish one-stop solutions for culture and business.



Schema Ontology Syntax	Schema Definition Syntax	Metadata Instance Syntax

Fig. 3. Structure of the Multi-Schema Metadata Format by Digital Vision Laboratories.

Digital Vision Laboratories[47] is also doing very interesting work. They have created a Multi-Schema Metadata Format (MMF) and a Metadata Mediation Protocol (MMP) as the basis for an electronic commerce mediator. Their initial goal was fairly straightforward: to include characteristics of merchandise (the dress should be a given colour, size, cost), as constraints in a catalogue based retrieval system. This goal was complicated by the fact that such catalogues may use different terms to describe the same thing. The customer is searching for a dress, which may be listed under *women's garments* in one catalogue and *ladies apparel* in another. They solved this problem building on the architecture outlined in the Warwick Framework to arrive at the schema above (fig. 3).

The above is another example of how the OCLC/NCSA approach is gaining wide implementation. It confirms how business applications are profiting from experience in organization in the library world. Their pragmatic solution to a problem in everyday shopping is of further interest, because it can potentially be useful in solving two important problems in the library field. One is multiple classifications for a single term, which serves as an excellent potential tool for entering into the mind sets of different cultures. A second is the problem of related terms. A reader is searching for a book on one subject. They notice that the book also deals with other related subjects. By using these related terms the reader typically discovers valuable new materials. This process which is presently manual could be automated using the new Metadata format outlined above.

All this points to a model that goes far beyond the initial search engines. Such a model will have at least seven layers, namely, i) the user, who has access ii) to a variety of views and a iii) tools for examining iv) an object of study to which they can then apply v) basic library metadata before entering upon vi) content negotiation metadata, in order to gain access vi) to relevant contents (fig. 4).

Fig. 4 A seven layered approach to meta-data.

To recognise why this is only the beginning of what is needed, a brief excursus on the structure of libraries is necessary. In the world of the great libraries the problems of meta-data are hardly new. For centuries, the great libraries had too much data to permit any one individual ever searching through every document, let alone read each one carefully. So reference rooms with at least five levels of meta-data were designed. Reference rooms contain 1) subject catalogues and classification systems, which provide the reader with a standardised set of terms, with clear indications where those terms fit in a hierarchy of ideas, i.e. references to both more universal concepts or Broader Terms (BT) and more specific or Narrower Terms (NT). Reference rooms also contain 2) dictionaries to provide readers with definitions of terms with which they are unfamiliar. They contain 3) encyclopaedias, which provide a slightly deeper insight into such unfamiliar terms and, of course, they contain 4) titles. These include a) card catalogues, b) (national) book catalogues and c) bibliographies. Book catalogues range from historical works, such as Heinsius to *Books in Print*, which are lists of titles pointing to more detailed literature (both primary and secondary) about those terms. Bibliographies are effectively a further sub-layer of meta-data insomuch as they establish links between primary works (level 6) and the secondary literature about those works (layers 7-10). Reference sections also contain 5) literature about that literature in the form of abstracts (which summarise quantity), reviews (which summarise quality) and citation indexes (which are bibliometric pointers to and, some would claim, indices of quality). The rest of the library contains 6)[48] the full contents of these books (primary literature) and 7-10) various levels of studies about these books, i.e. secondary literature (see fig. 3).

Library automation typically began by focussing on level 4) card catalogues and in some cases included samples of 6) full contents. In the past decade, work has begun on most of the other levels, namely, 1) classifications systems (e.g. Electronic Dewey); 2) dictionaries (e.g. the Oxford English and Websters); 3) encyclopaedias (e.g. the Britannica and even classics such as Thieme-Becker) and 5) citation indexes in the Humanities and Social Sciences etc. The latest advances in meta-data outlined above (fig.4) are effectively only subsets of level 4, with some references back to the subjects and classes of level 1.

A full treatment of meta-data will require a systematic correlation between all five levels of the reference sections of a library with the remaining five levels. A reader could then choose a term, see where it fit into different classifications in order to obtain a larger vocabulary, check the meanings thereof in dictionaries and/or encyclopaedias, search for titles on this topic, and then check abstracts, reviews and/or citation indexes before reading the actual books. Technologically, such a system is possible today. It will effectively bring the immense power of reference rooms in great libraries available to everyone on their desktop. Digital libraries are a wonderful idea but we need to begin with digital reference rooms. Otherwise it is like building wonderful houses without doors and windows. We need systematic entry and exit points (fig. 5).

Fig. 5. Preliminary diagram for a bigger picture with seven layers linking user to content, integrating ten levels of knowledge as developed in the SUMS framework.

To render the resulting meta-data lists more workable, all the materials in the top five levels of knowledge would be broken down in terms of questions. Hence a person interested in biographical materials would query only those subsets pertaining to who at each of the levels, whereas a person looking for chronological information would query only subsets pertaining to when. It should be noted, moreover, that this level of queries would only be used in very complex cases.

Traditionally one only went to a major library if the material being sought was not available locally. So too will it be with online queries. Many questions are very specific and can best be answered by going to specialised databases, which have grown enormously even during the past year (1996). For example, someone wishing to find out about films would go to the Cardiff database on that subject. These will account for a majority of simple questions. More complex questions will require more complex tools accordingly. To this end each of the initiatives outlined above should be seen as complementary. In some cases, a URL, URN, URI and/or an ISBD (ER) will be sufficient. MIME types will be essential for those wishing specific kinds of media, e.g. video or databases. Site Mapping might be a default strategy for all web- sites with more than 100 pages. Similarly abstracts could be a default strategy for someone needing to master a field with hundreds of articles and books, as could the use of some kind of authentication and rating tools. Only some will need to enter into all the complexities of a major meta-data system and even this would be rendered more accessible by indications of different levels of education for which the material was written. This would permit beginners to start with introductory literature and experts to enter at the appropriate level.

Further advances will require new levels of cataloguing for existing collections. For although distinctions between primary and secondary literature are well established in theory, in practice most libraries provide no systematic links between a given primary source and the four levels of secondary literature outlined in our schema. The research of Professor Beghtol (Toronto) suggests that narrative discourse analyses can help in the refinement of classification theory. This would entail elements such as non-random characters (including narrators), events (human or non-human), settings (places, times), completion (resolution, end) and perspective (voice, point of view) in order to identify whether texts were descriptive, narrative, argumentative, literary, poetic, scientific, didactic or conversational. Such new levels of order would allow the access methods for meta-data to be refined accordingly.

In light of the above it is easy to discern why the initial search engines and browsers had such primitive results. They ignored most of the knowledge framework which libraries have laboriously developed in the course of the past three thousand years. Browsers such as Yahoo relied almost solely on personal lists of terms (a non-standardised treatment of level 1). In this context it also becomes clear why digital libraries in the fullest sense require much more than a simple scanning in of the pages. The scanned works have to be translated and new links need to be made. It may take generations to achieve this new integration of knowledge that looms as a promised land, but the sooner we begin, the sooner we shall progress towards the goal.

7. Agents and Delegation

The notion of metadata has enormous implications. It is intimately related to a whole series of new buzzwords, chief of which is agents. Some futurists such as Nicholas Negroponte and Brenda Laurel assume that agents will effectively become electronic butlers who will do our work for us. Lurking in this over optimistic techno-idealism are dangerous assumptions, or at least temptations, notably that technology can replace essential human activities

If we return for a moment to the schema in figure five, it will be seen that a (digital) library effectively has three quite separate parts namely, a reference room, a section for facts (primary literature) and a section for interpretation (secondary literature). Traditionally a great deal of time has been wasted simply sifting through the analogue versions of reference rooms in order to seek out where one might get a copy of the actual facts.[49] Agents would be ideally suited to do most of that work of finding things (which will typically range from 25-95% of a scholar's time). The user, reader, scholar decides what they want. They delegate to the machine the challenge of using digital reference rooms until they have sifted out what is being sought. Hence in terms of figure five, computers are particularly suited for helping in section one of the library.

Potentially, of course, machines can do much more than find sources. As was noted earlier they can readily handle conditions, parameters, constraints. These features are already being explored for their applicability to rating systems and they could be extended to help in the process of verifying facts, the second realm of the digital library. An obvious way is through digital signatures. A more subtle way would be in comparing texts. If it is known that a student accessed 742 texts, then machines could do a word search to see whether plagiarism was entailed. Such techniques could equally be applied to scholars, and in the analysis of texts when one is trying to assess more closely the sources of a Montaigne, an Erasmus or a Dante.

These constraint tools can also help in the realm that was central in traditional scholarship, namely interpretation. At present we have spreadsheets which translate lists into charts such that we can see new patterns in the evidence. This ability is already generating new fields such as scientific visualisation and data mining. It takes little effort to see how this could be pushed much further. New image software such as IBM's Query by Image Content (QBIC), as well as products by Illustra (now Informix) and Excalibur, are beginning to permit machine detection of colours, patterns and shapes. Given the potentials of constraint language one could therefore delegate the machine to find all paintings with a *Virgin and Child*, all paintings with a given face, or even all paintings in a given "style", assuming of course one could define it with sufficient precision. In terms of figure five, computers can thus help in the third section of libraries as well.

Object-oriented programming is leading to a whole new approach to objects.[50] In the field of Computer Aided Design (CAD), for instance, a consortium led by Autodesk is developing the principle of industry foundation classes. Hereby, a door is treated as an object (in the computer sense), such that a door for a cottage automatically adjusts to the features of a cottage door, whereas a door in a skyscraper will automatically take on the characteristics of a door in such a building. In the parlance of salesmen, the door "knows" the shape that it has to take on in different environments, i.e. it is a "smart door." In the past, one had to draw each door anew. Now one simply invokes the door (as a computer object) and it automatically becomes what it has to become (reminiscences of Aristotle's notion of entelechy).The danger with this approach is that it feeds into the McWorld syndrome to which Barber[51] drew attention, whereby every Hilton around the world looks indistinguishable, whereby a suburb of Paris is effectively indistinguishable from a suburb in Germany or the United States.

Traditionally each country and even each city had its own variations on stock objects. For a time almost every column in a mediaeval church was uniquely carved. In secular architecture, a façade in Braunschweig was slightly different from those in Wolfenbüttel nine miles away, different again from each and every city within a hundred mile radius, including Hornburg, Hildesheim, Goslar, and Quedlinburg. Each of these variants can be seen as local constraints. If each local town enters their own values within a standardised framework, then CAD objects in Hanover can automatically enter the local features to doors and other elements. In short the next stage to universal foundation classes is to add cultural dimensions which adjust geographically and temporally (i.e. historically), such that one could see, for instance, what the local Renaissance style would have been.[52]

A parallel revolution is occurring in the field of maps.[53] Tile caching methods will soon allow users to zoom seamlessly from space and link with any spot on earth. This geographical information can be linked with global positioning systems, with Computer Aided Design (CAD) programs, with Area Management/Facilities Management, with historical view to produce whole new landscapes of knowledge.[54] Some see spatial techniques as essential metaphors for conceptual navigation through visualisations of knowledge.[55]

Ultimately this theme of globalisation and uniqueness needs to be extended to the realm of languages also. The same danger of a McWorld in terms of shapes is posed by the threat that we would have a McWorld where English was the only idiom of expression. Already, there are French critics who would have us dismiss the web because there is more English than French. With the advent of Unicode and important software such as the Tango Browser by Alis Technologies, over 90 languages are covered at present. This is, however, but a small fraction of the 6,000 languages presently in use around the world. Thus, added to the challenge of getting everything on line there is the greater challenge of getting it translated into as many languages as possible. Taken seriously, this challenge will take care of much unemployment.[56]

8. Learning

In light of the above some will no doubt agree that Negroponte was surely right in his description of a world where butlers will do our scholarly work for us. Others will at least ask: is there anything left to do? On reflection the answer is definitely, yes, there will be lots left for humans to do. Computers may be useful in finding *Virgins*, even valuable in finding their lower-case variants. However, this does not address the question of what to do when one finds them. New software may provide sense-making tools, but at a certain level the challenge of how to interpret the significance of what we find will always be an essentially human task. For in this task lies the realm of meaning which is central to being human.

To see this more clearly it is useful to recognise that the ten levels of knowledge in a library are also the ten areas of learning for an individual. Potentially they are also the ten areas of their scholarly activities. Learning in its deepest sense is about all levels of knowledge and about the process of organising all those levels into understandable patterns or more precisely patterns which increase our understanding and our wisdom. Seen in this way, it soon becomes clear that most of us have a very limited sense and also limited practice of learning. The interests of most persons and the work of most scholars belong to the third section of the library. We do internal analyses. How does that motor work? We do identifications and descriptions: What is that motor part? Who is that figure? What is that object? Where is that place? Or we do external analyses: Who is that figure related to stylistically or genealogically? What are other examples of that theme? Where are other paintings by the same artist, or similar paintings? Some of us do restorations. Some historians are particularly caught up with reconstructions. Most scholarship is secondary literature, commentaries on the deeds of others.

A minority of persons actually write books which belong to the primary literature section of the library. An even smaller minority write works which affect fundamentally the reference section of the library and paradoxically this is more true the further one ascends the levels of knowledge.[57] A certain number of persons (e.g. critics) produce partial contents of books (abstracts, reviews, citation indexes). A smaller number produce titles (librarians and cataloguers) or write standard encyclopaedias. Even fewer write our standard dictionaries and even fewer still affect the great classifications such as Library of Congress. It is perhaps no coincidence therefore that we frequently remember them in terms of their author's name: Bliss, Dewey, Ranganathan. And paradoxically there is an unexpected connection with getting back to that first level of knowledge and preoccupation with the first principles of knowledge in a philosophical sense that affects the very ordering of the layers. In this realm we find the philosophers, theologians and mystics who challenge us not just in terms of this or that interpretation or definition but rather in terms of our entire framework by which we understand who, what, where, how and why we are.

At the same time, the creation of terms, naming, organising them, making classifications is perhaps the most universal of all human activities. We all make lists to make sense of the world, to impose order on it. That is what the constructivists are on about. What they overlook is that most of us are too lazy to do this for purposes other than our purely personal satisfaction and we are quite happy to accept that someone else has taken the trouble to create a more universal scheme. A few of us make an effort to go beyond the accepted schemes. We name them thinkers and intellectuals. Only the rarest succeed in creating truly useful universally applicable schemes. Somehow it is only given to these few, an Aristotle, a Plato or a Leonardo, to propose an order worth remembering, worth trying to understand, worth trying to go beyond. We call them geniuses, spiritual leaders, wise men, shamans only confirming by our poverty of words our own distance from this category making transcendence.

9. Conclusions

Computers are transforming the meaning of education in the sense that most of the traditional drudgery of learning and scholarship can soon be delegated to electronic tools in anthropomorphized forms as aids, agents, avatars or even butlers. There is not a little irony in this trend. Nearly a half century ago visionaries such as Engelbart saw in computers a new hope for unleashing individual creativity. It was a noble goal based on a tantalising premise. If only we can provide everyman with the right tools then everyman can do anything. By this premise the word processor was to make everyman an author. Millions of copies of Word Perfect and Word have been sold. A corresponding surge of Nobel laureates in literature has not been evident. Similarly, millions of Computer Aided Design (CAD) packages have been sold, but not every owner of the software has become a great designer or a famous draughtsman. Soon there will be millions of video-editing packages, but the number of memorable video and film producers will not rise proportionately. Some will be tempted to dismiss this whole exercise as a mistake or see it as confirmation that commercial interests are truly the driving force behind these developments. It may be more fruitful, however, to suggest that the experiment is unfinished because certain vital ingredients are still lacking.

Traditionally we learn best from example. There has been so much enthusiasm over the new tools that many assume or even believe that example is no longer necessary. This is reflected in catchy phrases such as: "From the sage on the stage to the guide on the side", usually pronounced by key-note speakers who are very much centre-stage. More significantly it is reflected in the politics of our educational system. For example, in faculties of education even in major universities, those who are learning to teach may find no formal courses on computers, their uses or their implications, practical, or philosophical. As a net result, we end up with magnificent tools with practically no one around who is seriously equipped to teach their uses and potentials.

Instead, teachers are provided with all kinds of theories about what computers should do for children: how they should create computer supported intentional learning environments; help them to collaborate; encourage them to create their own categories, classifications, semantic networks and world-views; give them courage to construct their own knowledge frameworks and help them to assess each others' efforts in all these endeavours.

As noted earlier these are very noble goals. They epitomise the achievements of the greatest scientists, philosophers and theologians of all time. Yet there are two fundamental differences between these great individuals of the past and our students of the present. First, these outstanding thinkers all had great teachers. Aristotle had Plato. Grosseteste, the founder of Oxford University, had Gundissalinus. Thomas Aquinas had Albertus Magnus. Yet we now expect our students to achieve great things without teachers. Indeed, we are giving them tools for manipulating words and images, tools for interpretation (part three of the library), before they have experienced the existence of solid facts (part two of the library), and without the help of all the traditional pointers to knowledge (the reference room which is part one of the library.

Second, with the great thinkers of the past there was an implicit assumption that one began by mastering the best which existed, and did not replace this until one and had achieved something which went further. Hence, in science it was useful to accept the categories of an Aristotle until a Leonardo could propose a more encompassing alternative. It was valuable to continue with the world-view of Newton until Einstein could offer a richer alternative. In the humanities generally, and in sociology and education in particular, the constraints of *more encompassing* and *richer* seem to have been forgotten. It is as if the simple act of making categories and theories, of constructivism were sufficient in itself, were virtue, as if the process were more important than the result.

If we are right, herein lie some of the deeper reasons for the discrepancies between the hype about multi-media and everyday practice; why the computer revolution, which has been imminent for so long is still only in its infant stages. We have been so busy creating the tools for the building that we temporarily forgot about the need for doors and windows. We now need to apply these tools to all parts of our libraries, which are the collective memories of all our lives. We need to bring back into focus the example of the great minds who came before. We need to show students examples. For only if we learn to see how small we are in the aeons of achievement, will we ever have the humility to unleash the incredible potentials which these past periods offer for our future insights beginning now. And only then will computers truly transform the meaning of education.

Acknowledgments

I am deeply grateful to the Ontario Library Association for providing me with an office to continue my work. I thank warmly Eric Livermore and Arnold Campbell (Advanced Networks and HCI respectively at Nortel's Bell Northern Research Laboratory and Stuart McLeod (VP Technology, Bell MediaLinx) for a research contract and consultancy which gave me the "leisure" to produce this paper. This paper owes insights to generous comments by Chris Lilly (of W3), Misha Wolf (Reuters), Larry Masinter and Peter Pirolli (Xerox), Steve Cisler (Apple), Heiner Benking (Ulm) and an inspiring lecture by Douglas Engelbart. It builds upon insights gained at a three recent conferences: *W3 Conference on Internationalism and Multilingualism* (Seville, November 1996); *Museums and the Web* (Los Angeles, March 1997); *6th WWW Conference* (Santa Clara, April 1997). I thank three teachers who have helped to spark my thinking in this field: Keith Medley, John Volpe and John MacDonald. I am grateful to Professor Larry Moore, Hasan Murtaza and Rakesh Jethwa for kindly reading the paper and offering suggestions. Any errors in comprehending and representing the big picture which they are helping to realize, are entirely my own.

[12] The figures used in these examples make no pretence of trying to estimate true market value. The point of the exercise is to establish the scale of the enterprise.

[13] In this context, it is useful to recall the distinction made by Professor Dertouzos between information the noun and information the verb. Information the noun is the raw material: books, manuscripts and the like. Information the verb is the realm of interpretation: what we do with this material, the activities of knowledge workers. He estimates that information the noun is 10% of the economy and information the verb is at least 60% of the economy. Owning the manuscript is simple. Scanning it in is still relatively simple. Translating it is less simple. Understanding it is anything but simple.

[48] It will be noted that these six natural components of a library comprise the first six levels of knowledge in the SUMS framework.

[49] At Wolfenbüttel, one of the greatest research libraries of the world, it was jokingly said that scholars spend 95% of their time finding a rare source and 5% of their time actually reading it. In practice the mix depends largely on the level and kind of scholarship. If one is working on a new edition of a classic text such as Hamlet and one is using the accepted sources, then search time is limited to secondary literature. If one is trying to master a field, or determine the boundaries of a new field, then it could be as high as 95%. In many cases about a third to half one's time is also spent writing the results of one's readings.

[50] For another treatment of these problems see the author's "Frontiers in Electronic Media", *ACM Interactions*, New York, July 1997, (in press).

[51] Benjamin Barber, *Jihad vs. McWorld*, New York: Random House (Time Books), 1995. Some see globalisation as necessarily wrong and the local as an alternative: e.g. Jerry Mander, Edward Goldsmith et al., eds., *The Case Against the Global Economy: And for a Turn Toward the Local*, San Francisco: Sierra Club, 1996.

[52] These problems will be explored further in the author's essay, "Global Standardisation, Regionalism, and Individual Uniqueness", *Oz. Rivista internazionale di Utopie*, Rome, vol. 4, 1997, (in press).

[53] Michael Potmesil, "Maps Alive: Viewing Geospatial Information on the WWW," *Sixth World Wide Web Conference*, Santa Clara, April 1997, TEC 153, pp. 1-13. Cf. mpm@research.bell-labs.com

[54] To give some idea of the immensity of material involved a one meter scale map of the United States requires 3,300 CD-ROMS or approximately 2,112,000 megabytes.

[55] One of the pioneers in this field is Stuart Card, as in note 28 above. Cf. *Proceedings of the Workshop on Advanced Visual Interfaces*, Gubbio, 1996. See, also the work of Heiner Benking (Ulm), who has been working on new spatial visualisations using a cognitive Panorama with a magic cube (ZauberWürfel) which serves as a "bridge between literal, figurative-metaphorical, contextual and physical landscapes of meaning, allowing us to share also information beyond meso-scale. Cf. his lecture " The Necessary next Phylogenetic Step—World View Compositions," Konrad Lorenz Institut, Altenberg/Vienna, 1997.

[57] It is also ironic that when persons active in authoring these first five layers become too energetic they resemble secondary literature.

FLYING IN THE FACE OF INSTRUCTIONAL DESIGN (RATIONALE FOR THE CASE STUDY)

Rob Walker
Centre for Education and Change
Deakin University
AUSTRALIA
rob@deakin.edu.au

Abstract

This paper explains the educational rationale implicit in the adoption of a case study approach to course design. 'Case study' is seen as embodying a set of educational assumptions and an appropriate learning model for applying to the problem of how professional workers learn to improve their practice by active reflection on experience. 'Case study', we claim, is not just a way of organising collections of descriptive material but implicates specific, and perhaps contentious, educational values.

Introduction

This paper gives an account of our use of CDROM(1) in a distance education program. Changing Classrooms is a year-long unit of study in Deakin's fourth year Education program in which the course team has been experimenting for ten years with ways of 'breaking the grip of print' in distance programs of this kind. This has involved increasing use of photographs, audio and video tape, which in turn has led to the development of quite different student assignments. The most recent development has been a multimedia, case study of a school. 'Hathaway Primary School' is a CDROM, which provides an extensive and diverse collection of material forming the resource basis for a six to eight week period of study (around 70 hours of student time). 'Students' (who are almost all 'teachers') are guided through this material in the expectation that it will 'take them inside' Hathaway, the fictional name given to a real school in Sydney's inner western suburbs. In this paper our concern is with the educational issues that have arisen from our attempts to become active users of CDROM technology.

Multiple technologies

Accounts of this kind are often presented within a frame that treats a single technology as an introduced variable and the course itself as a one-dimensional outcome. This frame is readily recognisable by the questions it generates:

•What did it cost? •Do the students learn better/faster as a result? •Is it more efficient? •Could we do it? •What software would we need?

The narrative structure of this 'single input/simple outcome' model is one that underlies much vernacular curriculum history and is generally of the type:

-- HISTORY (This is what we used to do)
-- INNOVATION (Here comes the innovation and isn't it great!)
-- CHANGE (This is what we are doing now)
-- EVALUATION (Is it better/cheaper/faster? Where is the resistance to change?)

Implicit in this narrative structure is the assumption of the inevitability of the flight of the arrow of progress and an unhelpful conceptual separation of technology into its material and social aspects. Tempting as it is, to tell our story in this form would be to mislead, and since Alistair Morgan (1991) has already written a history of our course which emphasises the inextricably entwined nature of its social, political and curriculum aspects with its educational technology, we cannot easily or honestly retreat from the demand for a more complex view.

What does this 'more complex view' imply?

•Rather than seeing the story in terms of the impact of a single technical innovation ('Here comes CDROM'), we prefer to see it in terms of conjunction, even a collision, between multiple technologies, each of which has material and social aspects. •The first of these lie in the nature of the innovation itself, for digital technologies are inherently complex as media. We argue that they are not just a way of adding together fragments of existing media, but in themselves constitute something new. •In addition, as Bill Green, has pointed out (personal communication), case study too is a technology, especially in the way we use it as a way of organising our teaching. For we are not simply using 'case studies' as a means of illustrating concepts we have just taught, but as a device for smuggling an ideology, a set of theories and set of practices (mostly about research, but also about teaching) into the course. The term 'case study', as we use it in our course, has a powerful hidden curriculum. •The notion of the 'course team too is a technology in the sense that course organisation, curriculum, pedagogy and assessment are mediated and managed through it -- it is the primary means by which the university gets teaching done. •The fact that the CDROM is designed for use within a distance program (though it gets many other uses), sets it in a context. This context is one in which educational technology is conventionally framed in particular ways (Evans & Nation 1989). Whatever our intentions within the course team, the university frequently presents the innovation (especially to the outside the world) as evidence to justify its image of itself as innovative within this field. (A partial fiction in which we readily collude).

What are the key educational issues?

Multimedia or multimedium?

Digital technologies are inevitably plural -- the 'Hathaway' CDROM is 'multi-media' in that it includes, video, images plus sound plus transcript, photographs, drawings, plans, 3D models and a range of formats -- academic writing, newspaper clips, observational video, tv news reports, letters, proposals, interviews, student writing, school documents, official records and forms, statistical data, street maps, architectural drawings etc etc.

We have come, though, to see this collection as constituting something beyond bricolage; for the ease of movement between forms that digitisation allows in itself creates the basis of a new medium. We tend to describe the CDROM in terms of what is familiar (as we have just done), but its novelty really lies in its functionality; it is its search capabilites, its seamlessness and its capacity for generating the unexpected that define its distinctiveness.

Distance education as technology

Distance educators approach information technologies with ambiguous feelings. On the one hand these technologies appear to promise a means of escape from the constraints which have consigned distance education to a low status position within higher education. With universal access to the internet it appears possible to break the grip of print, the boredom of the lecture hall, the tyranny of distance, the oppression of the tutorial and to replace them with (at least) a new set of cliches. On the other hand, we suspect that these promises are too readily adopted by academic administrators (who are themselves rarely educational users of the new media) and who have in mind other agenda, most of which are focussed on issues of efficiency and control. Our location within a distance education context (an institution, a curriculum, a course and a set of practices) inevitably leads us to confront the dominance, within educational technology, of the notion of 'Instructional Design'. We are well aware that 'Instructional Design' is interpreted and practiced much more loosley within our university than in many other settings (in commerce, industry and the military, for instance) but nevertheless it is there (often disguised, distorted, obscured or invisible) and needs to be addressed.

Aims, but not objectives

We have chosen not to specify learning objectives but to limit ourselves to setting educational aims. We have a diverse student group (from beginning teachers to experienced professionals, primary, secondary and adult educators from all specialisms and subject areas) and we see our educational task as encouraging them to develop their professional judgement through critical reflection. This is to invoke an educational process that is quite different from that of instructional models. It is not uniform. It builds on personal knowledge, taking bias, prejudice and self-delusion at face value. It is open-ended and context-bound. It seeks to provoke people to identify blind spots in their perceptions and so to extend their possibilites in practice (rather than to replace their routines with new behaviours).

One the claims frequently made for instructional models is that, by insisting on the behavioural expression of outcomes, they always focus directly on what is learnt rather than on what is taught. But these outcomes are almost always defined by the instructor. A key issue in professional development is to get people to identify their own learning needs, a process that it is inevitably reflective and personal. Instructional design has the effect of making the curriculum objective, removing learning from areas of personal experience and making it freely available to all who are willing to subject themselves to the process. (Its origins in military training are, as Noble (1991) has so clearly shown, deeply inscribed in its practices.) In professional education our concern is less with behavioural outcomes and more with the improvement of professional judgement.

The nature of case study

Well researched case studies intentionally provide much more information than the learner can manage or understand, most of this information is fragmentary, unsystematic, ambiguous, unreliable, perhaps redundant, irrelevant or untrue. The learning tasks to which the material is aimed are often ill-defined and so difficult to assess. All the behind-scenes work done by course developers in the instructional design model is here left for the student to do, and so she frequently finds herself unsure of the task and overwhelmed by information, most of which seems partial, confusing, poorly arranged and of doubtful reliability or validity.

This is what we like about case studies, they are like real life!

Against competency

An instructional design model may be appropriate when we are trying to teach people particular responses to relatively technical problems but it requires that we are able to squeeze what we are trying to teach into a tight frame. In fact it is surprising just what diverse fields of knowledge can be made to fit the model, as military organisations have shown, often achieving success with the very people who have been failed by schools. However, there is a cost, for in some cases it is the very judgements and conceptual imagination that is required of instructional designers that are the things we want the learner, not the teacher, to learn.

While it presents itself as rational and straightforward, for the most part instructional design does not in itself model the ways in which teachers seem to learn (even though some might say that they should). Teachers, like other professionals and jpfs (Jean Lave's neat jargon acronym for 'just plain folks'), including parents, adults attempting to program the vtr, weekend chefs and gardeners, computer programmers, dancers, jazz musicians, beginning Morris dancers and supermarket shoppers, appear to learn more from experience than from instruction. Getting things wrong is often more instructive than getting things right. Knowing you have got it wrong, with what consequences, and why, is usually memorable.

Teachers learn from the experience of teaching, of seeing others teach, from talking, reading and thinking about teaching (see, for instance Nias 1989). It follows that if we can find credible ways of simulating this experience of experience then we may be able to accelerate and extend the process of 'natural' learning, rather than imposing an over-rational, and inappropriate, frame upon it. At the heart of this effort lies a deep concern, not with competency, which is a relatively trivial educational aim, but with improving professional judgement.

Reflexivity and Writing

In devising a case we must be sure that it seems real. Credibility is an important consideration, for if the case does not seem real then it will be difficult to engage reflexivity. Reflexivity is a key to understanding how we learn from cases/experience. It implies that we learn, not just from what we see and hear or read but from reflecting on what we feel, what we think and how we change as we learn. Hence writing is an important element in learning from cases, because in writing we have to make our own sense of things: we have to engage our own subjectivity in the process(2).

Case study and distance learning

It will be clear that the notion of learning implicit in this approach is somewhat different from the theories of learning implicit in instructional design models (see also Murphy & Taylor 1993). Learning from experience is not a free gift! For we learn, not from experience itself, but from the work we put into understanding the meanings that experience has for us(3). In this we cannot put personality to one side as a set of contingent variables. In learning from experience/case studies, the person who is the learner should be at the centre of the process, not to one side of it. Not everyone will learn the same things, to the same level and in the same ways. Much of what we learn will be about how we learn, and about ourselves, and others, as learners, and it will be coded in our memories as tacit rather than propositional knowledge. When we are successful our course will provide the ground for the telling of stories, for our students will build the experience of the course into the narratives of their lives. We will do so too.

At first sight this flies in the face of the conventions of distance learning, for the term itself seems to define the teacher as a person out of consideration. The very fact that there is little room for face-to-face interaction is read by many as depersonalising the process. Our experience has been the opposite. We have come to believe that, in fact, there is a greater potential for intimacy in distance relationships than there is in the seminar room. (This should not surprise anyone who has ever read a book, watched a film, had a telephone conversation or corresponded on the internet). In all face-to-face contact, but especially in teaching, most of us self-censor and selectively project aspects of ourselves to a remarkable extent (to the point where we often no longer realise that this is what we are doing). In classrooms this is markedly so, indeed for many young teachers 'learning to teach' means extensively (and sometimes painfully) self-editing their presentation of self in order to amplify and project a very limited range of their potential selves. Perhaps paradoxically, distance programs have more scope for engaging more of the person in the process of professional development than does conventional teaching.

Assessment versus reflexivity

Assessment plays a large part in conventional instructional design. The technology of test construction is highly developed, even if in practice it is often misused. Testing is of very limited value in the face of the aims we have set for ourselves because it removes responsibility for evaluation from the student, when what is important for the learner to develop is the capacity to test their understanding for themselves. This is not easy to achieve, but in sharing what they learn, they may come to a greater understanding than they can realise alone.

In contrast with instructional design models, case studies emphasise reflexivity, they draw on and attempt to integrate with prior learning, they take a view of knowledge as subjective (and hence value-related) rather than as objective and value-free (or 'technical'). Implicit in the idea of learning from case studies is that learning is a social rather than an individual experience, that the learner is best placed to evaluate what they have learned (and has a responsibility to do so) and that this is best organised with groups or teams rather than individuals in mind.

While case studies seem to fit well with our ideas about how teachers learn, there are a number of important considerations that need to be kept in mind:

•What you learn from case studies/experience cannot be pre-specified or easily generalised. •What you learn (how much and how well) will depend mostly on the questions you bring to the case, your persistence in pursing these questions and your imaginative capacity to transform them. •Your tutor/teacher/instructor may often seem evasive when you ask just what you must do and what you should learn (eg when you ask for the objectives of the exercise). They are not being evasive, they do not and cannot know the correct answers, for there are none (though there are some that may be incorrect). •In terms of feedback you should invite, expect and welcome critique but, since there are no right answers, correction should be restricted to factual questions. The aim of the tutor should be to help you sharpen your interpretations and analyses, suggest ways you might develop them, counter assertions you might make, stretch the logic of your arguments and comment on the way you organise and present your work. •Instructional design models tend to assume that what is correct is also true and right. Case study methods thrive on drawing distinctions between these different judgements.

Case Studies: frequently raised objections

Just as instructional design models conflate learning models with approaches to teaching, assuming that a positivist, empiricist way of thinking about one also provides the best way to approach the other, so too does case study. The differences between the two are therefore in part about different views of science, different ways of looking at the world and acting within it. It follows that many of the objections that are raised to case study methods of teaching derive from objections to case study as a method of research. Thus:

Case studies are not scientific, only anecdotal

Case studies are often seen to be only stories, everyday happenings presented in everyday language. At best they are descriptive but made complicated by the idiosyncracies and variability of human social behaviour. William Ferguson (???) has described this approach to teaching as 'Aesopic' (in contrast to teaching which is 'Socratic').

Case studies are not objective

How social science comes to terms with itself as both about social action and inevitably a form of social action has been a long running debate which is far from resolved(4). In educational research this debate often sufaces in the form of a relatively superficial debate between 'quantitative' and 'qualitative' approaches to research. 'Objectivity' is sometimes claimed as a consequence of adopting accepted conventions and procedures, but to do this is to hide the issue rather than to resolve it. Objectivity, as journalists and other writers know, is the consequence of a struggle to understand, not a consequence of acquiesence to convention. Objectivity and subjectivity are therefore best thought of, not as alternatives, but as two sides of the same coin. Objectivity results, not from the denial of subjectivity, but as 'conscious control of relevant biases' (CARE undated).

You cannot generalise from a case study

It is sometimes seen to be a constraint of case studies that they are locked in the particularities of the instant and the idiosyncracies of individuals, and so unable to provide knowledge that is transferable or capable of generating theory. In the context of the problems of education, especially education within large and complex organisations, this is of course also their strength. Case studies that are more than superficial have the capacity to stall any attempts that are made to generalise or theorise from a narrow conceptual base. Case studies are best used to counter generalisations, not to illustrate, exemplify or support them. What is most powerful about case study research is that it makes generalisation from the case more difficult, not that it makes it easier.

Case studies are always about other people's problems, not mine

Where simulated experiences, such as those provided by aircraft simulators, are quickly adopted by most participants as 'real', case studies of social situations are more difficult to create. They can take you up close to others, allowing you to experience vicariously their world, putting yourself in positions where you experience dilemmas as they experience them but equally they can be used to create distance -- providing wooden descriptions of situations which we find unbelievable or in which we see all those in the case as foolish, inept or acting unethically. Creating cases is therefore something of an art, and judging quite how complicated and ambiguous to make the information we present is always a difficult decision, since it requires us to balance verisimilitude and comprehension.

Often, conveying the 'reality' of the case is less important when we are dealing with social situations, because our aim is not primarily to create a believable mock-up but to provide the basis for analysis and discussion. The Hathaway case is like this in that we are aiming to create a situation in which you feel you 'know' the school and can discuss it with some understanding of its complexity. Giving you the feeling that you are actually in a classroom or walking down a corridor is not so important as giving you the capacity to resist simple interpretations of the school. In relating to you as the user of the CDROM, our primary concern is with your thinking, rather than with providing the illusion of you being in the here-and-now of the classroom, the corridor, the playground or the staffroom.

Case studies are always conservative

Good case studies, we believe, are those which present a picture that is complex and resists simple interpretation. It follows that they also tend to resist radical analysis or prescription. The more you know and understand about a situation, institution or organisation, the more difficult it is to change it. For every change you might suggest has to be seen in a complex social context; a system within which even small changes may have complex and amplified consequences.

Summary

Implicit in what we have written is the assumption that our aim is not to achieve learning. Our aim is not that you should know 'more', but that you should improve your capacity for judgement in relation to your professional work as a teacher, ie that you should 'know better'. Learning, in this sense, is not replicable, the best we can hope for is to come to terms with the limitations of our capacity to learn from our experience.

Abstract: This paper discusses the processes and problems related to designing educational content for the Web. It is suggested that the design process has to account for the types of knowledge we wish to convey in this medium, the characteristics of likely users of a coherent Web site, as well as the structures inherent to a range of different text genres, such as narrative, that might be included. In using the Web to deliver any form of content, we have to be aware of the potential as well as the limitations of this medium to provide access to an original knowledge base, for multiple users.

Introduction

In November 1995, the OLTC (Open Learning Technology Corporation) commissioned the author of this paper, to create a presence on the Web for delivery of educational content, to be published and disseminated via the EdNA (Educational Network of Australia), and administered by DEETYA (Department of Education, Employment and Training), to be on–line early April, 1996. The OLTC provided a three–four month time span for the writing of the project (December 1995–March 1996). The project, now complete, can be found at: http://www.oltc.edu.au/cp/default.html (Wild, 1996).

The scope of the completed work, entitled *Learning with software: Pedagogy and practices*, is similar to that of a traditional book. However, in most other respects, authorship in this technology is very different to the writing of a book, with the creation of this Web space encompassing fundamental issues concerned with using a new medium to represent knowledge—issues such as, creating appropriate hypermedia structures in knowledge, determining effective levels of user– or learner–control in this medium and maximising user–orientation in hyper–space.

The intention was to provide access to a expandable and dynamic knowledge base for teacher's professional development in the area of information technology pedagogy and practices. The content was not available in other forms, and necessitated delivery of different types of knowledge—experiential, empirical (research based) and theoretical. The Web was chosen as the delivery medium primarily for its ubiquity and insignificant publication costs; however, it was not chosen for its instructional effectiveness; nor was it chosen as an ideal medium for carrying a range of knowledge types. In this context, the Web was found to be restricting, despite its ever–developing capacity to carry multimedia materials and information, and its growing provision for various levels of complexity in learner–material interactions.

In using the Web to deliver any form of content, we have to be aware of the potential as well as the limitations of this medium to provide access to an original knowledge base, for multiple readers or users. Empirical and theoretical knowledge can be communicated as with the publication of traditional reference materials, with accessibility provided by keyword searches, browsing, and hierarchical and semantic linking. Much of the experiential knowledge might be represented as narrative, since this type of knowledge largely originates in story form. Yet narrative derives its usefulness as a means of communication from associative processes—how does one narrate stories about experiences so that they have meaning for all types of readers, whatever their cultural background or geographical location? More importantly, how does one represent narrative, a linear and cohesive genre, in a medium that typically encourages fragmentation and the breaking down of information into separate, discrete and disparate parts? Furthermore, an experiential knowledge base is by definition, extensible and volatile—it is apt to change, grow and be subject to redundancy: How can these processes be managed in the Web? The discussion of these and other issues and questions form the basis of this paper.

Working With The Web

The nature of the World Wide Web has attracted a great deal of rhetoric in favour of its potential to provide for a student–centred model of learning, where the learner is both intrinsically motivated and active in the learning environment (Becker & Dwyer, 1994). Indeed, at first glance there is much in the Web that appeals to educators— for example, the hypermedia information structures in the Web allow for the chunking of information, a feature that, in light of information processing theories of working memory, might be seen to support the cognitive processing of knowledge (Biggs & Moore, 1993). There have also been suggestions that in providing for browsing and thematic exploration, the Web facilitates higher order cognitive processes, such as transfer and knowledge application (Jacobson & Spiro, 1995; Oliver, Herrington, & Omari, 1996); whilst at a more conceptual level, there has always been a case made for hypertext mirroring the ways in which much of human thinking occurs—by association rather than linearly or procedurally (Burton, Moore, & Holmes, 1995; Bush, 1945; Minsky, 1975). Furthermore the Web, in terms of being a dynamic, extensive and extensible information base, provides for the ultimate in resource–rich learning.
